Synthesis and Optoelectronic Properties of Hexa-peri-hexabenzoborazinocoronene

Jacopo Dosso, Jonathan Tasseroul, Francesco Fasano, Davide Marinelli, Nicolas Biot, Andrea Fermi, and Davide Bonifazi*

Abstract: The first rational synthesis of a BN-doped coronene derivative in which the central benzene ring has been replaced by a borazine core is described. This includes six C C ring-closure steps that, through intramolecular Friedel–Crafts-type reactions, allow the stepwise planarization of the hexaarylborazine precursor. UV/Vis absorption, emission, and electrochemical investigations show that the introduction of the central BN core induces a dramatic widening of the HOMO–LUMO gap and an enhancement of the blue-shifted emissive properties with respect to its all-carbon congener.

Graphene is one of the leading materials in today’s science,[1] but the lack of a band gap limits its application to replace semiconductors in optoelectronic devices.[2] To overcome this limitation, the replacement of C=C bonds by isostructural and isoelectronic bonds such as polar B=N[3] is emerging as an effective strategy to open a band gap in monatomic graphene layers.[4] To the best of our knowledge, only one example of a BN-doped covalent network featuring a regular doping pattern has been described so far through surface-assisted reaction.[5] Otherwise, only sheets containing B, N and C (h-BNC) over wide compositional ranges randomly distributed in domains of h-BN and graphitic phases have been prepared so far.[6] At the molecular level, notable examples include BN-doped polycyclic aromatic hydrocarbons.[7] Among those, the isolation of the first hexa-peri-hexabenzoborazinocoronene (HBBNC)[8] from pyrolysis of a borazino precursor by Bettinger and co-workers is an important example in view of the creation of hybrid graphenes featuring controlled BN-doping patterns (Figure 1). However, the stunted solubility of this molecule limited in-depth structural and physical studies.

Herein we describe the first rational synthesis of B$_3$N$_3$-doped benzocororone 1 that, being soluble in common organic solvents, allowed a direct comparison of optoelectronic properties with those of its full-carbon congener. Generally, controlled BN-doping patterns in PAHs are obtained through bottom-up synthesis involving aniline-type precursors[3] that undergo planarization through intramolec-ular electrophilic aromatic substitution reactions, simultaneously forming C B and B N bonds in the presence of BCl$_3$ and a Lewis acid. At the synthetic planning level, this consideration guided us to contemplate at first a convergent path relegating the formation of the HBBNC core to the last step (Scheme 1, path A). However, the scarce yield for preparing the triamino-spherand precursor forced us to defer this synthetic path and to anticipate the B$_3$N$_3$ formation in an earlier step.

Figure 1. HBC and its borazino-doped analogue HBBNC.
This would lead to the HBBNC core through two, three or six ring-closure reactions involving the aryl substituents (Scheme 1, paths B, C, and D). As we have predicted a potential instability of the strained borazine precursors of paths B and C, a decision was made to undertake plan D. Commonly, the planarization of covalently preorganized aryl moieties into PAHs is obtained through Scholl-type oxidative ring-closure reactions. However, the vulnerability of the borazine ring under oxidative conditions directed us to consider a Friedel–Crafts-type substitution as the planarization reaction. This line of thought led us back to hypothetical borazine precursors bearing appropriate leaving groups (LG) at the ortho positions of the B-aryl substituents (path D) that, triggered under given conditions, can yield reactive arylium species. It is hard to not notice that the presence of ortho LG additionally exerts protection to the B-atom centers, making the borazine precursor enough stable to be handled. Embracing this synthetic strategy, we prepared a borazine precursor bearing F and peripheral xylyl moieties as LGs and solubilizing groups, respectively.

Following previous procedures, hexafluoro borazine 5 was thus obtained after reaction of 4-xylyl aniline 3 with BCl3 upon subsequent addition of difluoro-ArLi 4 (Scheme 2). A crystal of borazine 5, suitable for X-ray diffraction, was obtained by vapor diffusion of MeOH to a CH2Cl2 solution of 5. The quasi-orthogonal arrangement of the aryl moieties forces the F substituents to nest atop the B atoms (B···F = 2.922 Å), negatively shielding the electrophilic center. Capitalizing on the Friedel–Crafts ring-closure reaction of fluoroarenes developed by Siegel and co-workers, borazine 5 could be planarized into HBBNC 1 (5 % yield, 61 % per C C bond formation) in the presence of [iPr3Si···CB11H6Cl6] and Me2SiMes2 at 110 °C in PhCl operating in a Schlenk line. Together with HBBNC 1, partially fused BN-derivative 7 was obtained as major product (17 % yield), suggesting that the ring closure proceeds stepwise with the last aryl fusion likely being the rate-determining step. All-carbon congener HBC 2 (Scheme 2) was also prepared for comparison purposes (Supporting Information, Scheme S1).

Molecule 1 was characterized using NMR, UV/Vis, and IR spectroscopy and HR-MALDI spectrometry. At first, HBBNC 1 was unambiguously identified by HR-MALDI through the detection of the peak corresponding to the molecular ion at m/z 837.3652 (C60H42B3N3+, calc.: 837.3658). Solution 1H-NMR spectra further confirmed the structure of HBBNC 1 (Figure 3 B). Specifically, coupled Hα and Hβ protons appear as triplet (8.05 ppm) and doublet (8.55 ppm), respectively, whereas one singlet (8.58 ppm) is observed for Hc proton. An analogous resonance pattern (Figure 3 A) is also observed for reference 2. Notably, the presence of the inner B3N3 cycle in 1 induces a high-field shift of the proton resonances with respect to those of 2, suggesting a significant decrease of the magnetic anisotropic properties of the B3N3-doped derivative. Analogously, a remarkable high-field shift was also observed for the boron resonance (at 30.59 ppm) in the 11B-NMR spectrum (Supporting Information, Figure S24) of 1 when compared to that of precursor 5 (at 34.9 ppm).

To further corroborate the chemical structure of 1, crystals suitable for X-ray diffraction analysis were obtained by vapour diffusion of iPrOH to a C6H6 solution of 1 (Figure 4 A).
The X-ray analysis confirms the nearly flat shape of the BNC framework, displaying a similar structure to that of all-carbon congener 2, with shorter BN lengths (1.433–1.442 &). To appraise the effect of the BN doping on the aromatic p-surface, we further determined the charge distribution of the crystal structure of 1 in the form of ESP calculated with Gaussian 09 at B3LYP/6-31G(d,p) level of theory (Supporting Information). As expected, the p-surface of 2 is negatively charged showing the presence of a homogenous p-cloud above and below the HBC skeleton. On the other hand, 1 displays a great charge polarization of the p-surface, with the N and B atoms negatively and positively charged, respectively, and the outer hexaphenylene rim negatively charged. These results are consistent with the expected ambipolar character of the molecule.[15] UV/Vis absorption and emission properties in CH$_2$Cl$_2$ of molecules 1 and 2 are displayed in Figure 5 and Table 1. The lowest-energy electronic transition of 1 appears in the near-UV (375 nm) at significantly higher energy with respect to that of 2 (446 nm). In line with theoretical predictions,[4a,b, 11] this finding suggests that the B$_3$N$_3$-doping widens the molecular optical band gap (DE$_{opt}$ = 0.53 eV). Furthermore, the absorption bands of 1 show noticeable vibrational substructures evidencing a high degree of rigidity of the molecular skeleton.[16]

[a] Recorded in air-equilibrated CH$_2$Cl$_2$ at RT. [b] Calculated from the higher-energy maxima of the emission spectra in air-equilibrated CH$_2$Cl$_2$ at RT ($\varepsilon_{opt}$ = 1240/λ). [c] Quinine sulfate in 0.5 m H$_2$SO$_4$ was used as the standard (F$_{QS}$ = 0.546). [d] Recorded in a 1:1 CH$_2$Cl$_2$ : CH$_3$OH v/v rigid matrixes at 77 K (Supporting Information, Figure S31). [e] Fitting of the emission decays. Values in [%] indicate the weight of each exponential component in the biexponential fitting. [f] Calculated for O$_2$-free solutions.
Consistently, the emission spectra (Figure 5) in solution at room temperature reflect the same trend, with the intense emission peak of 1 ($l_{\text{max}} = 404$ nm, FWHM = 0.43) significantly blue-shifted with respect to that of 2 ($l_{\text{max}} = 485$ nm). Notably, the FWHM value significantly increases to 0.77 in O$_2$-free solutions. Phosphorescence spectra at low temperature (Figure 5) showed long-lasting emission profiles ($\tau_{\text{phos}} = 4$ s) with 1 providing the highest-energy triplet emission ($l_{\text{max}, \text{phos}} = 492$ and 570 nm for 1 and 2, respectively).[17] Furthermore, 1 displays appreciable solid-state fluorescence emission in the violet–blue region ($l_{\text{max}} = 426$ nm vs. $l_{\text{max}} = 487$ nm for 2) at room temperature (Supporting Information, Figure S32).

Cyclic voltammetry (CV) measurements showed a quasireversible first oxidation wave at approximately 1.46 V vs. SCE in CH$_2$Cl$_2$ for HBBNC 1 (Figure 6; Supporting Information, Figure S32).

Figure 6. Left: Frontier orbital energies estimated from the CV and photophysical data for 1 and 2. Reduction potentials of the triplet excited states are evidenced by the narrower optical energy gaps ($E^{1/2}_0 = E^{1/2}_{1/2}$). FC$^+$/FC = 0.46 V vs. SCE; 4.8 eV vs. vacuum. Right: HOMO and LUMO profiles for 1 and 2 at B3LYP/6-31G(d,p) level of theory (GAUSSIAN09).

In conclusion, we have described the first synthetic methodology to prepare a soluble HBBNC molecule following a planarization strategy based on a Friedel–Crafts reaction. This involves the simultaneous formation of six C·C bonds starting from a hexafluoroborazine precursor. First, X-ray diffraction confirmed the presence of the inner B$_3$N$_3$ cycle, with short B·N bond lengths. The remarkable UV absorption, strong blue–violet singlet emission, and green phosphorescence of this class of hybrid B$_3$N$_3$-doped molecules are in line with the theoretical predictions. Given the importance and ubiquity of graphene in scientific research, the development of novel synthetic strategies leading to hybrid graphene derivatives featuring precise doping patterns will undoubtedly lead to new discoveries and applications in materials science. In this respect, the synthesis and photo-physical study of this long-awaited compound marks an important milestone toward the understanding of the optoelectronic properties of doped molecular graphenes.
