Abstract:
Novel electron-deficient chiral hypervalent iodine reagents were prepared in good overall yields. The reactivity and stereoselectivity of these reagents in oxidative rearrangements of alkenes to α-aryl ketones was investigated. The results show that the new reagents have good reactivity and generate products with high enantiomeric excess.

The chemistry of hypervalent iodine reagents has witnessed a massive growth and development in the 21st century. The extensive interest in hypervalent iodine reagents is attributed to their powerful oxidizing properties, along with their easy handling, commercial availability and benign environmental impact. Their synthetic applications include oxidation, halogenation, amination, C–C bond formation, heterocyclization and rearrangement reactions.1,2,3 Recently, many efforts were devoted to the development of hypervalent iodine catalyzed chemical transformations.4 The catalytic cycle relies on the re-oxidation of an iodine(I) species, mainly iodoarenes, into the corresponding hypervalent iodine compounds in the presence of a stoichiometric oxidant. Hydrogen peroxide, oxone, m-chloroperbenzoic acid, sodium perborate, and Selectfluor5 are commonly used terminal oxidants in such catalytic transformations. The utilization of chiral iodoarenes as organocatalysts for different enantioselective transformations is a fast-growing research area and several approaches have been published recently.5

Chiral hypervalent iodine(III) reagents have been very successfully used in stereoselective synthesis and received much attention.6 Fujita7 and Ishihara8 initially published the synthesis and use of chiral hypervalent iodine reagents based on lactic acid. Many reactions have been investigated using these chiral reagents and in some of them very high stereoselectivities have been obtained. We also have contributed to that development and published highly stereoselective oxyaminations9 and also the first stereoselective rearrangements based on chiral, lactic acid-based iodine(III) reagents.10 The investigation of more recent rearrangements employing additional orthoesters to generate α-aryl esters as reaction products proved to be less efficient with the known lactic acid-based iodine(III) reagents. We therefore decided to prepare more reactive versions of the reagents 1 by the attachment of an electron-withdrawing group such as a trifluoromethyl substituent (R = CF₃) in the para-position to the iodine (Figure 1). This should enhance the electrophilicity of the hypervalent
iodine reagents 2 (R = CF₃) as compared to the unsubstituted reagents 2 (R = H). With other hypervalent iodine(III) derivatives we have already shown that the addition of CF₃ groups in para position to the iodine(III) moiety enhances their reactivity.¹¹

Such reagents have been prepared by the route shown below starting from the commercially available 3-nitro-5-(trifluoromethyl)phenol 3 (Scheme 1), through which the novel key building block, 2-iodo-5-(trifluoromethyl)benzene-1,3-diol 6 was accessed. Reduction of the nitro group in 3 to the corresponding amino derivative, 3-amino-5-(trifluoromethyl)phenol 4 was achieved in 97% yield with disodium sulfide in ethanol. Diazotation of 4 was followed by treatment with a saturated aqueous solution of copper sulfate leading to the formation of 5-(trifluoromethyl)benzene-1,3-diol 5 in 73% yield. The desired iodoarene 6 was obtained in 39% yield via the reaction of diol 5 with elemental iodine.¹²

![Scheme 1: Synthesis of 2-iodo-5-(trifluoromethyl)benzene-1,3-diol 6](image)

Having the key intermediate 6 in our hands, we could proceed to achieve the synthesis of the target hypervalent iodine reagents of type 2. Following literature procedures, the iodoarene 6 was transformed into the lactate based chiral iodoarene derivative 1a in 98% yield under Mitsunobu reaction conditions. Basic hydrolysis of the diester 1a afforded the dicarboxylic acid 1b in 80% yield. Activation of the dicarboxylic acid 1b followed by the reaction with 2,6-diisopropylaniline and 2,4,6-trimethylaniline afforded the amides 1c in 71% and 1d in 83% yield, respectively (Scheme 2). Finally, the chiral iodoarenes were oxidized to the corresponding hypervalent iodine reagents 2a and 2c using Selectflour® in a mixture of acetonitrile and acetic acid. The iodine compound 2d could not be isolated despite many attempts.
Several efficient methods for the synthesis of α-aryl substituted carbonyl compounds through metal-catalyzed cross coupling reactions of ketones are known. We have reported an efficient metal-free method for synthesizing α-arylated carbonyl compounds via an enantioselective oxidative rearrangement of alkenes using stoichiometric chiral hypervalent iodine reagents (Scheme 3). Based on this reaction we have now developed new chiral iodoarenes for accessing α-aryl carbonyl compounds.

Initially, we explored the oxidative rearrangement of alkene 7 using different chiral iodine(III) reagents as stoichiometric oxidants (1.2 eq). To evaluate the reactivity of the newly prepared hypervalent iodine reagents 2a and 2c, we studied the oxidative rearrangement of the alkene 7 by reagents 2a, 2c and the previously reported reagents 2e – 2g (Table 1). Reagent 2a (Table 1, entry 1) with the trifluoromethyl substituent showed comparable reactivity and similar enantioselectivity to the previously reported reagents with either a methyl substituent 2e or without substituent 2f (Table 1, entries 2 and 3). Yields range between 45 and 50% while the enantiomeric excess is between 87 and 92%. All reagents produce the same enantiomer of 8 (R-configuration), but in each reaction a small amount (5-15%) of ketone 9 is detected as a side product. Reagents 2c and 2g with amide functionalities in the side chain showed much lower reactivity (Table 1, entries 4 and 5), while the enantioselectivity is almost identical.
Table 1: Different iodine(III) reagents 2 in the rearrangement of alkene 7

Furthermore, the potential of the oxidative rearrangement of alkene 7 using different iodoarene catalysts (20 mol%) in presence of a stoichiometric oxidant was investigated. The catalytic reactions had to be performed at a higher reaction temperature as the oxidation to iodine(III) is too slow at low temperature. Initially, several iodoarenes were screened in the presence of one equivalent m-chloroperbenzoic acid (mCPBA). Substantial amounts of 9 were generated while the overall yield was very low. Enantioselectivities were also low (45-76% ee, see supporting information). Different oxidants were also investigated. Although Selectfluor® showed reasonable reactivity, fluorinated by-products 11a and 11b were always produced by direct reaction with the alkene. Some selected reaction conditions are summarized in Scheme 4.
Scheme 4. Rearrangement with chiral iodoarene catalysts.

Yields of the rearranged reaction product 8 never exceeded 20%, so no catalytic conversion was achieved. Moreover, if the reaction is performed without iodoarene using 1 eq. mCPBA, only compound 9 was formed in 71% yield indicating a strong background reaction under the reaction conditions. Further details are found in the supporting information.

In summary, we have synthesized new trifluoromethyl-substituted lactic acid-based hypervalent iodine derivatives, which showed similar behaviour and unfortunately no advantage to the unsubstituted reagents with regards to the stereoselective rearrangement investigated here.
