Abstract. Background. Metastasis suppressor 1 (MTSS1) is a multifunctional cytoskeletal protein. Recent research showed that MTSS1 is a potential tumor suppressor in many types of cancer cells, including kidney and bladder cancer cells. However, the clinical implication of MTSS1 in human bladder uroepithelium cell carcinoma (BUCC) and its potential in suppressing BUCC tumorigenesis remains undetermined. In the present study, the expression of MTSS1 in human BUCC tissue samples, and correlations between MTSS1 and pathological grade and stage of the tumors were examined in BUCC specimens. The function of MTSS1 in BUCC progression was explored. Materials and Methods: The mRNA and protein expression of MTSS1 were examined in 68 BUCC tissue samples with matching adjacent normal bladder tissues using quantitative real-time PCR and western blotting. Furthermore, the bladder cancer cell line 5637 was used to determine the anticancer effect of MTSS1. Results: Lower MTSS1 mRNA expression was recorded in BUCC tissues compared to normal bladder tissues. A lower MTSS1 mRNA level was observed in tumors with high clinical stage and with high pathological nuclear grade. Likewise, MTSS1 protein expression in normal bladder tissue was significantly higher than that in BUCC tissue. The protein level of MTSS1 significantly negatively correlated with clinical stage and pathological nuclear grade of BUCC. Cumulative survival curves indicated that MTSS1 expression was negatively correlated with survival time: patients with a high level of MTSS1 had significantly longer survival time than those with a low level of MTSS1 (p<0.001). Overexpression of MTSS1 reduced BUCC cell proliferation, cell-cycle progression and colony formation, but had no influence on BUCC cell apoptosis. Conclusion: Overexpression of MTSS1 suppresses BUCC development, providing a novel perspective for BUCC tumorigenesis and a potential therapeutic target for BUCC.

Bladder uroepithelium cell carcinoma (BUCC), which accounts for more than 90% of all bladder cancers, is the most common malignancy of the urinary tract and the ninth most common malignancy in the world (1). BUCC is a highly heterogeneous disease, with different histological subtypes and varying prognosis. The overall and 5-year cancer survival rates were significantly different among patients with different pathologic grading, histologic type and AJCC stage of BUCC (2). Although wide use of advanced imaging and surgical techniques have improved the clinical outcome of patients with BUCC, no specific indicator has been found that predicts morbidity and postoperative recurrence of BUCC in patients.

Metastasis suppressor 1 (MTSS1) was originally identified as a metastasis-suppressor protein with 759 amino acids. Its C-terminus is identical to the 356 amino acids encoded by the MTSS1 gene, which is found on human chromosome 8q24.1 and encodes a 5.3-kb mRNA and a polypeptide predicted to be an actin-binding protein of 356 amino acids with homology to the Wiscott-Aldrich Syndrome protein family (3, 4). MTSS1, also known as missing in metastasis (MIM), MIM-B or basal cell carcinoma-enriched gene 4 (BEG4), was mainly located in the cytoplasm and may be involved in cytoskeletal organization (5). MTSS1 was originally identified as a protein down-regulated in metastatic bladder carcinoma cell lines (3), and evidence has indicated that MTSS1 expression may be correlated with different types of cancer (6-10).
We demonstrated that the MTS1 was a potential tumor suppressor in human bladder cancer and kidney cancer cells in our previous studies (11, 12). Thus, MTS1 may act as a multifunctional molecule in tumorigenesis and metastasis. However, the role of MTS1 in the regulation of the cellular behavior of bladder cancer is still very much an open question. In the present study, we investigated the expression of MTS1 in a cohort of human bladder cancer tissues and its correlation with pathological grade, clinical stage and long-term survival of patients. Furthermore, we examined the biological effect of MTS1 on migration and invasion in bladder cancer cells in vitro.

Materials and Methods

**BUCC specimens.** A total of 68 (41 males and 27 females) pairs of BUCC and normal bladder tissue samples from newly diagnosed patients who underwent total cystectomy or transurethral resection of bladder cancer from May 2014 to December 2015 at Peking University Cancer Hospital were snap-frozen in liquid nitrogen immediately after surgery. The average age of patients was 52.7 ± 10.4 (range=26-78) years. In the cohort, 52 (76.5%) and 16 (23.5%) cases were staged as non-muscle-invasive bladder cancer (NMIBC) and muscle-invasive bladder cancer (MIBC), respectively. Pathological grades of the cohort were low grade in 48 cases (70.6%) and high grade in 20 (29.4%). The present study was performed according to the Declaration of Helsinki and was approved by the Ethics Committee of Peking University Cancer Hospital, and written informed consent was obtained from each patient.

**Cell cultures.** Bladder cancer cell line 5637 was obtained from the American Type Culture Collection (Manassas, VA, USA). Cells were cultured routinely in RPMI-1640, supplemented with 5% fetal bovine serum, 100 U/ml penicillin and 50 μg/ml streptomycin (all Gibco, Carlsbad, CA, USA). All cell lines were grown in a humidified incubator at 37°C and 5% CO₂.

**Expression vectors and lentiviral infection.** Lentiviral transfected with MTS1 expression plasmid (NM_014751) (GV287-RBM5) and plasmids containing scrambled control sequence (GV287) were constructed by GenceGene Company (GeneGene, Shanghai, China). Bladder cancer 5637 cells were infected with MTS1 overexpression lentiviral vectors and negative control lentiviral vectors according to the manufacturer’s instruction, with 1 μg DNA for 4x10⁵ 5637 cells in a 24-well plate. Five hours after the transfection, the cell culture medium was replaced with 10% fetal bovine serum.

**Bromodeoxyuridine labeling.** For the bromodeoxyuridine (BrdU) labeling, cells were plated into 96-well culture plates at a 2x10⁴ cells per well in 100 μl cell culture medium and maintained at 37°C. The cell growth rate was determined using a BrdU cell proliferation ELISA kit (Roche Diagnostics, Indianapolis, IN, USA) according to the manufacturer’s instructions after 1 and 4 days. Each experiment was performed in triplicate and repeated three times independently.

**Cell-cycle analysis.** For cell-cycle analysis, cells were seeded on 6-well plates at 80% confluence and incubated at 37°C for 24 h. The cells were harvested, washed with ice-cold phosphate buffered saline and resuspended in ice-cold 70% ethanol for 30 min. The cells were then treated with 10 mg/ml RNase A at 37°C for 30 min. The cells were stained with 10 mg/ml propidium iodide (Sigma, St. Louis, MO, USA) for 30 min. The DNA content was measured by flow cytometry.

**Colony formation in soft agarose gel.** For the cell colony formation assay, cells were seeded into 6-well plates at 800 cells per well and cultured at 37°C for 14 days. The medium was replaced every 3-4 days. Cells were washed twice with phosphate-buffered saline, fixed with paraformaldehyde, stained with Giemsa (Sigma) for 20 minutes, and washed with ddH₂O three times. The plates were photographed with a microscope. Each experiment was performed in triplicate and repeated three times independently.

**Cell apoptosis detection.** For cell apoptosis detection, cells were seeded on 6-well plates at 80% confluence and incubated at 37°C for 24 h. The cells were harvested, washed with ice-cold phosphate-buffered saline and resuspended in staining buffer. Flow cytometry was performed to analyze apoptosis. An annexin V-allophycocyanin (APC) stain assay (eBioscience, Vienna, Austria) was performed using the manufacturer’s protocol, and the apoptotic cells were analyzed by flow cytometry.

**RNA extraction and quantitative real-time polymerase chain reaction.** Total RNA was extracted from tissues or cells using TRIzol® reagent (Invitrogen Life Technologies, Carlsbad, CA, USA). FastQuant RT Kit (With gDNAse kit and SuperReal Premix Plus (SYBR Green) (TIANGEN BIOTECH, Beijing, P.R. China) were used. The PCR primers used were as follows: MTS1 forward: 5’-ACTGGGAAATCTGACACACTA-3’, MTS1 reverse: 5’-GACCT GACTGCTAAGGGAC-3’; glyceraldehyde 3-phosphate dehydrogenase (GAPDH) forward: 5’-TGACTTCAACGCGACCCAG-3’, GAPDH reverse: 5’-CACCTGGTGTGATGAGCAA-3’. PCR cycling conditions were as follows: an initial denaturation period at 95°C for 15 min, followed by a two-step PCR program consisting of denaturation at 95°C for 10 s and annealing/extension at 60°C for 32 s for 40 cycles. All samples were normalized against the internal control (GAPDH) and analyzed using the 2−ΔΔC₅₀ method.

**Western blot analysis.** Total protein was extracted from the cells or tissue using lysis buffer containing protease inhibitors. Thirty micrograms of protein from each sample were loaded on 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis. The gels were electrophoresed, and then transferred onto polyvinylidene difluoride membrane (GB Healthcare, Buckinghamshire, UK), and blocked with 10% non-fat milk in Tween/Tris-buffered salt solution [20 mM Tris-Cl, pH 7.5, 0.15 M NaCl and 0.05% Tween-20] for 1 h. Following incubation with the antibody to MTS1 (Santa Cruz Biotechnology, Inc., Santa Cruz, CA, USA) at 4°C overnight, the membrane was washed and incubated with IRDye® 800CW Goat anti-rabbit IgG secondary antibody at room temperature for 2 h followed by detection using a LiCor Odyssey gel imaging scanner (LI-COR Biosciences, Lincoln, NE, USA). To verify equal loading of protein, the blots were re-probed with a primary monoclonal antibody against GAPDH (Proteintech Group, Inc., Chicago, IL, USA).

**Statistical analysis.** Quantitative analysis of western blot was performed using the GelDoc-2000 Imaging System (UVi Company, Cambridge, UK). For protein expression level, the protein ratio (band density of study protein/band density of GAPDH) was considered as 100% in normal bladder tissues, and that of the other tissues was
expressed as a percentage of that of the normal bladder tissues. Comparison between groups was performed using one-way analysis of variance followed by all pairwise multiple comparison procedures using Bonferroni test and Student t-test or nonparametric test. In addition, Spearman correlation was used for comparison and estimation of correlations between MTSS1 protein expression levels and clinicopathological parameters. Survival curves were constructed using the Kaplan–Meier method. All data are presented as the mean ± standard deviation, and a value of p<0.05 was regarded as significant.

Results

Differential expression level of MTSS1 mRNA in BUCC and normal bladder tissues. The clinical and pathological characteristics of patients are shown in Table I. In order to compare the mRNA levels of MTSS1 in human BUCC and normal bladder tissues, total RNA was isolated from bladder tissues of 68 patients with BUCC and normal bladder tissues. The transcript level of MTSS1 was examined using qRT-PCR. The mRNA level of MTSS1 in BUCC tissues was significantly lower than that of normal bladder tissues. Furthermore, the mRNA level of MTSS1 was higher in NMIBC than MIBC, and lower MTSS1 mRNA levels were seen in BUCC with high pathological grade (p<0.05) (Figure 1).

Expression profile of MTSS1 protein in BUCC and normal bladder tissues. To further determine MTSS1 expression status in BUCC tissues, the protein level of MTSS1 in BUCC and normal bladder tissues were determined. As shown in Figure 2, decreased MTSS1 expression was seen in BUCC tissues compared to normal bladder tissues, and negatively correlated with clinical stage of BUCC (MIBC vs. NMIBC, p<0.05). The protein level of MTSS1 was also significantly negatively correlated with pathological grade of BUCC (high grade vs. low grade, p<0.05).

Decrease of MTSS1 expression was a predictor of poor survival of patients with BUCC. Kaplan–Meier survival analysis was used to determine the overall survival of

MIBC: Muscle-invasive bladder cancer, NMIBC: non-muscle-invasive bladder cancer. Data are the mean±SD, median (range) or number (%).
patients according to MTSS1 expression. Regardless of
cancer classification of MIBC and NMIBC, patients with
low MTSS1 expression had significantly shorter survival
than those with high MTSS1 expression (Figure 3A).
Furthermore, regardless of cancer grade, patients with low
MTSS1 expression also had significantly shorter survival
than those with high MTSS1 expression (Figure 3B). These
findings suggest that a decrease of MTSS1 expression in
bladder cancer predicts poor survival.

**Overexpression of MTSS1 reduced bladder cancer cell proliferation, cell-cycle progression and colony formation in vitro.** To explore the role of MTSS1 in bladder cancer cell proliferation, the 5637 cells were infected with MTSS1 overexpression lentiviral vectors and control lentiviral vectors. As shown in Figure 4, both the mRNA and protein expression levels were significantly up-regulated in 5637 cells after infection with the lentiviral vectors for MTSS1 overexpression. The BrdU proliferation assay was conducted to confirm the effect of MTSS1 overexpression on bladder cancer cells proliferation. As shown in Figure 5A, overexpression of MTSS1 reduced cancer cell proliferation significantly. Cell-cycle analysis and colony formation analysis were used to examine if MTSS1 overexpression influences bladder cancer cell growth. Figure 5B demonstrates that there was a significant increase in the rate of G2/M phase cells when MTSS1 was overexpressed, but there was no significant influence on cells in the S and G1 phases. Moreover, 5637 cells showed significantly less colony formation when MTSS1 was overexpressed (Figure 5C and D).

**Up-regulation of MTSS1 had no influence on apoptosis of bladder cancer cells.** To further elucidate the role of MTSS1 in bladder cancer cell apoptosis, 5637 cells infected with
Figure 4. Overexpression of metastasis suppressor 1 (MTSS1) in 5637 cells. The relative expression of MTSS1 mRNA significantly increased in 5637 cells after infection with MTSS1 overexpression lentiviral vectors. Con: 5637 cells without any treatment. NC: 5637 cells infected with negative control lentiviral vectors, and OE: 5637 cells infected with MTSS1 overexpression lentiviral vectors. B: Western blot analysis shows that MTSS1 protein level was significantly increased in the OE cells compared to NC cells. n=3 per group, *p<0.05 vs. NC group.

Figure 5. Up regulation of metastasis suppressor 1 (MTSS1) reduces cell proliferation. A: Quantitative analysis of bromodeoxyuridine (BrdU)-positive cell number was reduced in 5637 cells transfected with MTSS1 overexpression lentiviral vectors (OE) compared to the negative control lentiviral vector (NC) group. B: The quantitative analysis demonstrated that overexpression of MTSS1 significantly reduced the number of cells in the G2/M phase. C: OE cells formed fewer and smaller colonies per plate than the NC cells after 14 days seeded. n=3 per group, *p<0.05 vs. NC group. Con: 5637 cells without any treatment.
MTSS1 overexpression lentiviral vectors were subjected to annexin V-APC staining and flow cytometric analysis. Figure 6 demonstrates that MTSS1 overexpression in 5637 cells had no significant effects on the cell apoptosis rate.

Discussion

BUCC is one of the most common types of cancer, and an estimated 74,000 new cases are diagnosed per year. Since the molecular heterogeneity of BUCC is considered one of the most important factors responsible for large variation in response to clinical treatment, molecular diagnosis becomes more and more important in patients suffering from BUCC (13). In our previous study, we confirmed reduced expression of MTSS1 in human bladder cancer tissues using immunohistochemical analysis and also found a decrease in the mRNA expression in bladder cancer cell lines (12). In this study, we further confirmed decreased expression of MTSS1 in bladder cancer tissues and cell lines, especially in MIBC and high-grade BUCC. We demonstrated that low MTSS1 expression was a predictor of poor patient survival, and overexpression of MTSS1 reduced BUCC cell proliferation, cell-cycle progression and colony formation, but had no influence on BUCC cell apoptosis.

The role of MTSS1 in cancer diagnosis and progression has been elucidated. There are multiple published studies indicating cancer-suppressive functions of MTSS1 in a variety of cancer models. Kayser et al. found that the expression of MTSS1 significantly increased in non-small-cell lung carcinomas compared to normal lung, and MTSS1 expression was inversely correlated with cancer stage and histological grading. In addition, patients with low MTSS1 expression had a significantly worse outcome (14). Zeleniak et al. demonstrated that primary pancreatic ductal adenocarcinoma displayed higher MTSS1 expression levels than did metastatic pancreatic ductal adenocarcinoma (15). Another report also showed that loss of MTSS1 expression was associated with lymph node metastasis and poor differentiation of hilar cholangiocarcinoma (16), and high expression of MTSS1 suppressed the invasive, migratory, growth and adhesive properties of breast cancer cell lines (17). Similarly, data from our previous study demonstrated MTSS1 expression to be reduced in human kidney cancer cells, and to be inversely correlated with the growth, invasion, adhesion and migration of kidney cancer cells (11).

However, there are conflicting data on whether MTSS1 expression is an indicator of good or poor prognosis in patients with advanced cancer. In hepatitis B-related hepatocellular carcinoma, elevated MTSS1 expression was found to be associated with cancer metastasis and poor prognosis (18). Up-regulation of MTSS1 expression in colorectal cancer tissues was also significantly correlated with poor differentiation, tissue invasion, high preoperative carcinomaembryonic antigen level, presence of lymph node metastasis and high TNM stage (19).

Interestingly, our present data showed an increase in the proliferative potential of BUCC cells with decreased MTSS1 expression, but intrinsically overexpression of MTSS1 did not result in any difference in apoptosis. This suggested that MTSS1 mainly functions as a specific proliferation suppressor protein in BUCC, regulating cell proliferation and cancer growth. The mechanisms for down-regulation of MTSS1 in BUCC are not fully understood. Actin polymerization plays a very important role in cell polarization, cytokinesis and cell adhesions, which is ultimately implicated in a variety of stages of cancer progression. Multiple studies revealed that MTSS1 may act as a cytoskeletal scaffold protein to regulate cytoskeletal dynamics through interaction with other proteins. It can regulate cell motility by modulating different actin-related protein (ARP)2/3 activators (20). Overexpression of MTSS1 increased the formation of lamellipodia, membrane ruffles, and filopodia-like structures (21). In addition, MTSS1 was reported to behave as a sonic hedgehog-responsive gene, which association with the Gli complex during both development and tumorigenesis (22). Methylation is also known to be involved in the down-regulation of MTSS1. Yamashita et al. found when gastric cancer cells were treated with the demethylating agent 5-aza-2'-deoxycytidine, MTSS1 expression level increased significantly (23).

In summary, our current study demonstrated that MTSS1 plays an important role in BUCC tumorigenesis and development. These findings enrich our understanding of the molecular function of MTSS1 underlying BUCC...
progression, and is useful for understanding the role of MTSS1 in the proliferation of BUCC cells. MTSS1, therefore, could be a promising diagnostic biomarker and therapeutic target for BUCC. Further studies are necessary to determine MTSS1-related signaling pathways in BUCC progression.
