ABSTRACT. A series of complexes $[\text{Et}_4\text{N}][\text{Ln}(\text{NCS})_4(\text{H}_2\text{O})_4]$ ($\text{Ln} = \text{Pr}, \text{Tb}, \text{Dy}, \text{Ho}, \text{Yb}$) have been structurally characterized, all showing the same structure, namely a distorted square antiprismatic coordination geometry, and the Ln–O and Ln–N bond lengths following the expected lanthanide contraction. When the counterion is Cs^+ a different structural motif is observed and the 8-coordinate complex $\text{Cs}_5[\text{Nd}(\text{NCS})_8]$ isolated. The thorium compounds $[\text{Me}_4\text{N}]_4[\text{Th}(\text{NCS})_7(\text{NO}_3)]$ and $[\text{Me}_4\text{N}]_4[\text{Th}(\text{NCS})_6(\text{NO}_3)_2]$ have been characterized and high coordination numbers are also observed. Finally, attempts to synthesize a U(III) thiocyanate compound has been unsuccessful; from the reaction mixture a heterocycle formed by condensation of five MeCN solvent molecules, possibly promoted by U(III), was isolated and structurally characterized. In order to rationalize the inability to isolate U(III) thiocyanate compounds, thin-layer cyclic voltammetry and IR spectroelectrochemistry have been utilized to explore the cathodic behavior of $[\text{Et}_4\text{N}]_4[\text{U}(\text{NCS})_8]$ and $[\text{Et}_4\text{N}][\text{U}(\text{NCS})_5(\text{bipy})_2]$ along with a related uranyl compound $[\text{Et}_4\text{N}]_3[\text{UO}_2(\text{NCS})_5]$. In all examples, the reduction triggers a rapid dissociation of $[\text{NCS}]^-$ ions and decomposition. Interestingly the oxidation chemistry of $[\text{Et}_4\text{N}]_3[\text{UO}_2(\text{NCS})_5]$ in the presence of bipy gives the U(IV) compound $[\text{Et}_4\text{N}]_4[\text{U}(\text{NCS})_8]$, an unusual example of a ligand-based *oxidation* triggering a metal-based *reduction*. The experimental results have been augmented by a computational investigation, concluding that the U(III)–NCS bond is more ionic than the U(IV)–NCS bond.

Introduction

One methodology for the treatment of legacy, current and future nuclear waste is the Partition & Transmutation concept,¹ whereby the actinides (An) are separated from the lanthanide (Ln) fission products, which then undergo neutron bombardment reactions to form radioisotopes of much shorter half-lives that ease the burden on final storage. The difficult scientific challenge is separating the Ln 4f-elements from the An 5f-elements, in particular the minor actinides Am and Cm, as the 5f-orbitals drop in energy, becoming more core-like and thus resembling the lanthanides. One strategy that has seen success is by solvent extraction mechanisms where a specifically designed ligand, most successfully 2,6-bis(5,6-dialkyl-1,2,4-triazin-3-yl)pyridines and derivatives,² will preferentially coordinate to the actinide over the lanthanide,³ and some evidence for enhanced covalency in the An 5f systems has been presented.⁴ Experimentally a number of studies of U(III) and Ln(III) using N-donor ligands of varying denticity have been reported, and changes in bond lengths interpreted as evidence for a more covalent U–N bond.⁵ One interesting ligand type that has been investigated is the thiocyanate ion. It can be used in liquid-liquid extractions for the actinides as the stability constant for higher order complexes $[\text{Am}(\text{NCS})_2]^+$ is higher than that for the corresponding Eu complex (e.g., $\beta_2 = 4.19$ for Am and 1.93 for Eu).⁶ $[\text{A336}][\text{SCN}]$ (A336 = tricaprylmethyl ammonium) is a task-specific ionic liquid of sufficiently low viscosity to be used without utilizing a separate extractant, and substantial distribution ratio enhancements have been reported; although, the mechanism is unknown.⁷

The solution-based separation data, however, do not give information upon the solid state structures of the Ln or An thiocyanate compounds and structural studies are required to verify these observations. Lanthanide thiocyanate complexes are well reported in the literature and display a rich coordination chemistry.⁸ Early lanthanides favor higher coordination numbers such

as 10 in [ⁿBu₄N]₃[Ln(NCS)₂(NO₃)₄] (Ln = Ce,⁹ Nd¹⁰) whilst coordination number 9 is found in [Ln(18-crown-6)(NCS)₃] (Ln = Eu, Tb).¹¹ Coordination number 8 is common in structures as diverse as [ⁿBu₄N]₃[Ln(NCS)₄(NO₃)₂] (Ln = Nd, Dy, Yb),¹² [Ph₃PNH₂][Sm(NCS)₄(DME)₂],¹³ [Me₄N]₅[Ln(NCS)₈].2Sv (Ln = La, Ce, Pr, Nd, Sm, Eu, Gd, Tb and Dy; Sv = C₆H₆),¹⁴ the ionic liquids [Bmim]₄[Ln(NCS)₇(H₂O)] (Bmim = 1-butyl-3-methylimidazolium; Ln = La, Pr, Nd, Sm, Eu, Gd, Tb, Ho, Er, and Yb),¹⁵ and [C₆mim]₅[Dy(NCS)₈] (C₆mim = 1-hexyl-3-methylimidazolium),¹⁶ [Et₄N]₄[Ce(NCS)₇(H₂O)],¹⁷ [Et₄N]₃[La(NCS)₆(H₂O)(MeOH)],¹⁸ [Et₄N][Ln(NCS)₄(H₂O)₄] (Ln = Nd, Eu)¹⁹ and K[Ln(NCS)₄(H₂O)₄].3KNCS.2H₂O (Ln = Nd, Lu).²⁰ Coordination numbers 7 in [Et₄N]₄[Ln(NCS)₇].C₆H₆ (Ln = La, Pr)²¹ and 6 in [ⁿBu₄N]₃[Ln(NCS)₆] (Ln = Y, Pr, Nd, Sm, Eu, Gd, Dy, Ho, Er, Yb, Lu)²² or [Et₄N]₃[Ln(NCS)₆].S (Ln = Er, Yb; S = aromatic solvents)²³ have also been reported. In general, these data illustrate the expected lanthanide contraction in both coordination numbers and bond lengths.

For the actinides, structurally characterized thiocyanate complexes are scarce but required for Ln/An differentiation; notably, high coordination numbers are prevalent. For example, the 10-coordinate complex [ⁿBu₄N]₃[Th(NO₃)₃(NCS)₄],²⁴ 8-coordinate complexes [Et₄N]₄[An(NCS)₈] (An = Th,²⁵ U²⁶ or Pu¹⁷) or [Me₄N]₄[Np(NCS)₈]²⁷ and the 7-coordinate geometry in [Th(NCS)₄(DIPIBA)₄] (DIPIBA = ⁱPrCONⁱPr₂)²⁸ are known. Throughout all the 4f and 5f compounds, structural studies have shown that the bonding is more ionic, via the harder N atom. Moreover, the M–N–C angle is much smaller than that typically seen for transition metals, which can also be attributed to the increased ionicity in the f-block compared to the d-block metals.²⁹ Upon coordination to the f-block metal, the N≡C and C–S bond changes only slightly,

suggesting little reorganization in the π -framework of the ligand and thus only σ -bonding from the nitrogen.

We have recently reported an in-depth study of $[\text{Et}_4\text{N}]_4[\text{An}(\text{NCS})_8]$ (An = Th, U),³⁰ and reinvestigated the oxidation state of the uranium center in $[\text{Et}_4\text{N}][\text{U}(\text{NCS})_5(\text{bipy})_2]$.³¹ We now turn our attention to U(III) thiocyanate complexes that have not been reported to date, especially as $[\text{Et}_4\text{N}]_4[\text{Pu}(\text{NCS})_8]$ was synthesized via oxidation of a Pu(III) starting material.¹⁷ In this contribution we present structural studies of $[\text{Et}_4\text{N}][\text{Ln}^{\text{III}}(\text{NCS})_4(\text{H}_2\text{O})_4]$ (Ln = Pr, Tb, Dy, Ho, Yb), $\text{Cs}_5[\text{Nd}(\text{NCS})_8]$ and $[\text{Me}_4\text{N}]_4[\text{Th}(\text{NCS})_7(\text{NO}_3)]$, along with unsuccessful attempts to stabilize and isolate chemically reduced U(III) thiocyanate complexes. Thin-layer cyclic voltammetry and IR spectroelectrochemistry were employed to explore the redox behavior of U(IV) and related U(VI) compounds in more detail. The experimental work is supported by a computational study on the putative homoleptic U(III) compound.

Results and Discussion

Lanthanide structural studies. In our experiments, we used a two solvent system to grow single crystals and reproducibly isolated $[\text{Et}_4\text{N}][\text{Ln}(\text{NCS})_4(\text{H}_2\text{O})_4]$ {Ln = Pr (**1**), Tb (**2**), Dy (**3**), Ho (**4**), Yb (**5**)} rather than hepta- or octathiocyanate complexes; presumably this is due to the intrinsic ionic nature of the bonding and the excess of water present. The structure of **1** is shown in Figure 1 whilst **2-5** are in S1-S4; pertinent bond lengths are collated in Table 1 and Table S1. The asymmetric unit contains two 8-coordinate lanthanide ions surrounded by four thiocyanato anions and four coordinated water molecules in a distorted square antiprismatic environment;

there are no significant differences in the metric parameters between the two molecules. The average metal–nitrogen and metal–oxygen bond distances decrease with the increasing atomic number of the metal ion, as expected, whilst the average Ln–O distances are shorter than the average Ln–N bond distances. The N≡C and C–S bond lengths are the same as those found in the related uranium compounds³⁰ Given that Nd and Eu analogues [Et₄N][Ln(NCS)₄(H₂O)₄]¹⁹ and a similar lutetium complex,²⁰ K[Ln(NCS)₄(H₂O)₄]·3KNCS·2H₂O, have been structurally characterised, we can compare the bond lengths through the series (Table 1) and show that the lanthanide contraction is indeed evident in these compounds. However, it is worth noting that the Lu example has a different arrangement of the ligands so that two water molecules and two thiocyanato ligands are *trans* in the square of the square antiprism, whilst all other compounds have a *trans* and *cis* arrangement; this influences the Ln–O bond length the most.

Notably, the hydrogen atoms on the coordinated water molecules in **1-5** are involved in hydrogen bonding to the sulfur atom of an [NCS]⁻ ion. The S...O distances range from 3.208(2) – 3.288(2) Å, and in line with other examples of this weak hydrogen bonding in the literature.³²

Tb (2)	2.436(3)	2.392 (3)	This work

Dy (3)	2.428(5)	2.385(4)	This work
Ho (4)	2.412(2)	2.369(2)	This work
Yb (5)	2.394(2)	2.360(3)	This work
Lu ^a	2.3309(17)	2.4086(15)	20

^aThe geometry of [Lu(NCS)₄(H₂O)₄]⁻ has an all *trans* arrangement, whereas all others are *cis* and *trans*.

If the counterion is changed from Et₄N⁺ to Cs⁺ a different structural motif is observed and the coordination polymer Cs₅[Nd(NCS)₈] (**6**) isolated in the same solvent mixture as for **1-5**. The structure is shown in Figure 2. The geometry at the Nd center is intermediate between a cube and square antiprism, whilst the Nd–N bond lengths are in the range 2.498(19) – 2.573(7) Å, that is very similar to [Et₄N][Nd(NCS)₄(H₂O)₄].¹⁹ The structure features numerous Cs⁺⋯E (E = N, C, S) contacts that give a complex packing arrangement as shown in Figure 3.

Figure 2. Molecular structure of **6**. Thermal displacement at 50% probability. Selected bond lengths (Å): Nd(1)–N(1) 2.564(8); Nd(1)–N(2) 2.570(7); Nd(1)–N(3) 2.516(8); Nd(1)–N(4) 2.573(7); Nd(1)–N(5) 2.551(7); Nd(1)–N(6) 2.519(7); Nd(1)–N(7) 2.511(8); Nd(1)–N(8) 2.498(19); Nd(1)–N(8A) 2.498(15).

Figure 3. Packing of **6** along the crystallographic *c*-axis. Green polyhedral = Cs⁺; orange = Nd³⁺.

All the complexes have also been characterized by IR and Raman spectroscopy (Figure S6-S7), as the number of N≡C stretches is diagnostic of the geometry. Thus, for a square antiprismatic symmetry, three Raman-active $\nu(\text{C}\equiv\text{N})$ stretches ($A_1 + E_2 + E_3$) and two IR stretches ($B_2 + E_1$) are expected. In **1-5** three bands are observed at ca 2115, 2090 and 2080 cm^{-1} in the Raman spectra. In the infrared spectra only a broad peak is observed, but the shift in frequency of the C≡N bond stretch is in keeping with the change in the size of the lanthanide ion, as has been noted previously.²⁰ Dissociation of $[\text{NCS}]^-$ was not observed, as revealed by the

absence of the band at 2060 cm^{-1} . For **6** two bands are evident in the IR spectrum, and the Raman spectrum shows two bands at 2063 and 2052 cm^{-1} .

Table 2. Selected vibrational spectral data for **1-6**, measured in the solid state.

Complex	IR / cm^{-1}		Raman / cm^{-1}

Actinide structural studies. In comparison to the lanthanides, actinide thiocyanate compounds are much rarer. In order to expand the library of these compounds, we have prepared some thorium compounds. Thus, the reaction of $\text{Th}(\text{NO}_3)_4$ with 8 equivalents of NaNCS and 4 equivalents of Me_4NCl in MeCN reproducibly afforded the 9-coordinate mixed ligand species $[\text{Me}_4\text{N}]_4[\text{Th}(\text{NCS})_7(\text{NO}_3)].2\text{MeCN}$, **7**; the structure is shown in Figure 4. Upon repeating this

synthesis, we also obtained a structure that was disordered and it was possible, with some restraints, to refine this to 95% of 7.2MeCN and 5% of $[\text{Me}_4\text{N}]_4[\text{Th}(\text{NCS})_6(\text{NO}_3)_2] \cdot 2\text{MeCN}$, **8**. The structure of **8** is shown in Figure 5. With caution, we can compare the structural parameters with those known for $[\text{Bu}_4\text{N}]_3[\text{Th}(\text{NO}_3)_3(\text{NCS})_3]$. The average Th–N and Th–O bond lengths are essentially invariant as are the N≡C and C–S bond lengths, consistent with the ionic bonding of these ligands. The infrared spectrum of **7** show bands associated with the nitrate at 1480 cm^{-1} and the $\nu(\text{N}\equiv\text{C})$ at 2041 cm^{-1} .

Our attempts to synthesize a U(III) thiocyanate complex have not been successful. Reaction of $[\text{UCl}_3(\text{py})_4]$ (ref.³³) at $-78\text{ }^\circ\text{C}$ or the reduction of $[\text{Et}_4\text{N}]_4[\text{U}(\text{NCS})_8]$ with a variety of reducing agents, such as Na/Hg, K or $\text{NaC}_{10}\text{H}_8$ repeatedly failed to give any isolable uranium thiocyanate compounds. We have tried to follow the reduction with UV-Vis spectroscopy in a cuvette. Upon addition of the reagents an immediate precipitate is formed and all color bleaches from the solution. In a Schlenk flask at $-78\text{ }^\circ\text{C}$ we also see the same effect and the solid produced shows no N=C stretches in the IR spectrum. However, with the reducing agent being KC_8 in MeCN, a few colorless single crystals were isolated, and this shown to be heterocycle **9** (Figure 6), formed by condensation of five MeCN molecules. The mechanism of the formation of this unusual byproduct is discussed further in Supporting Information (Scheme S1), though it is worth noting that U(IV) amides trimerizes MeCN,³⁴ whilst the Lewis acidic U(III) ion has been known to cleave THF (ref.³⁵), Et_2O (ref.³⁷) and reductively couple MeCN.³⁸ Whilst it could be possible that U(III) rapidly

reduces $[\text{NCS}]^-$, this is unlikely as free thiocyanate can be used as a reducing agent³⁹ but complexed thiocyanate is readily oxidized to the corresponding radical.³⁰

The 2,2'-bipyridine (bipy) ligand is well known to be redox active,⁴⁰ and several actinide complexes have been reported in the formal metal(III),⁴¹ metal(IV),⁴² and inconclusive⁴³ oxidation states and with singly or doubly reduced bipy ligands. We therefore attempted the reduction of $[\text{Et}_4\text{N}][\text{U}(\text{NCS})_5(\text{bipy})_2]$ with alkali metal reducing agents, in an effort to generate complexes with either a U(III) ion, or U(IV) coordinated by a reduced bipy (radical anion). However, no isolable uranium compounds were obtained in any solvent used and free neutral bipy was the only species identified by ^1H NMR spectroscopy.

Figure 6. X-ray structure of **9** with displacement ellipsoids at 50%. Selected bond lengths (Å) and angles (°): N1–C2 = 1.3861(12); N1–C6 = 1.3170(13); C2–C3 = 1.3609(14); C3–C9 = 1.4230(14); C3–C4 = 1.5240(14); C4–C5 = 1.5326(14); C5–C6 = 1.5022(13); C6–N7 = 1.3230(13); C9–N10 = 1.1518(15); N7–H7B = 0.895(14); N7–H7A = 0.935(15), C6–N1–C2 = 117.62(8); C2–C3–C4 = 121.02(9); C3–C4–C5 = 106.34(8); C4–C5–C6 = 111.63(8); C5–C6–N1 = 122.12(9).

Spectroelectrochemical studies on uranium compounds. Intrigued by the inability to isolate any chemically reduced U(III) compounds, we turned to a study of the cathodic behavior of [Et₄N]₄[U(NCS)₈] using spectroelectrochemistry; our previous work focused mainly upon the

oxidation of this species.³⁰ It must be stressed that the cathodic responses of this family of U–NCS complexes are strongly affected by adsorption and electrode passivation. The cathodic potentials read from TLCV are reliable, as the electron transfer can directly be identified by the corresponding infrared spectral changes observed during the electrolyses; we have taken advantage of this to accurately determine the potential of the broad, poorly defined cathodic peak ($E_{p,c} = -1.80$ V vs Fc/Fc⁺) from conventional CV measurements.³⁰ To further evaluate the use of TLCV, we have also examined [Et₄N][U(NCS)₅(bipy)₂] and the uranyl compound [Et₄N][UO₂(NCS)₅] which also show broad CV responses due to slow reaction kinetics and/or limited by the solubility of electrochemically produced species.

The thin-layer cyclic voltammogram of [Et₄N]₄[U(NCS)₈] is shown in Figure 7, and the reduction potential is $E_{p,c} = -1.38$ V vs Fc/Fc⁺. This is much less negative than that originally obtained from the conventional CV measurements ($E_{p,c} = -1.80$ V),³⁰ which in light of the TLCV experiment is erroneous. During the reduction of [Et₄N]₄[U(NCS)₈], the broad parent $\nu(\text{C}\equiv\text{N})$ band at 2048 cm⁻¹ decreases in intensity and a new peak rises at 2059 cm⁻¹, which can be assigned to free [NCS]⁻.⁴⁴ We have recently reported a spectroelectrochemical study of Na[NCS] under the same experimental conditions³⁰ which conclusively demonstrates the identity of this species. U^{III}-NCS compounds could be coincident with the free [NCS]⁻ ion but a different line shape would be expected. Apparently, the addition of one electron triggers dissociation of all π -donor thiocyanate ligands and decomposition of the compound. Guided by this result we repeated the chemical reduction of the U(IV) compound in the presence of excess NaNCS but failed again to isolate any U–NCS containing product. It is clear that the thiocyanate ion does not stabilize the lower oxidation state of uranium effectively.

Figure 7. Left: Thin-layer cyclic voltammogram of $[\text{Et}_4\text{N}]_4[\text{U}(\text{NCS})_8]$ against Fc/Fc^+ determined in MeCN at 293 K, with $\sim 0.1 \text{ M}$ Bu_4NPF_6 as the supporting electrolyte, at $\nu = 2 \text{ mV s}^{-1}$. (The depicted scan shows oxidation of decamethylferrocene, $\text{Fc}^*/\text{Fc}^{*+}$, used as the internal standard; two cycles were applied to exclude any potential drift.) Right: IR spectral changes in the $\nu(\text{C}=\text{N})$ region accompanying the one-electron reduction of $[\text{Et}_4\text{N}]_4[\text{U}(\text{NCS})_8]$ in MeCN/ Bu_4NPF_6 at 293 K within an OTTLE cell. Blue spectrum: before the reduction at -1.38 V vs Fc/Fc^+ ; red spectrum: after the reduction.

We next looked at the redox processes of $[\text{Et}_4\text{N}][\text{U}(\text{NCS})_5(\text{bipy})_2]$, as the π -acceptor bipy ligand may allow for the isolation of a stable U(III) compound, or become reduced itself. Under the

TLCV conditions (Figure 8), there is a clearly defined reduction step at $E_{p,c} = -0.80$ V (vs Fc/Fc⁺). Due to the coordination of the π -acceptor bipy ligand, the reduction potential is significantly less negative compared to homoleptic [U(NCS)₈]⁴⁻. IR spectroscopy shows that upon the reduction the parent bands at 2036 cm⁻¹ and 2077 cm⁻¹ are replaced by a new band at 2059 cm⁻¹, again indicating free [NCS]⁻ and decomposition of the putative U(III) compound. Interestingly, upon monitoring the one-electron oxidation of [Et₄N][U(NCS)₅(bipy)₂], the IR spectra reveal the loss of the withdrawing bipy ligands, as judged from the appearance the $\nu(\text{C}\equiv\text{N})$ band at 2048 cm⁻¹ belonging to [Et₄N]₄[U(NCS)₈] (cf. Figure 7). As expected, the coordination of the bipy ligand weakens significantly upon the oxidation. The formation of [Et₄N]₄[U(NCS)₈] is also in line with the slightly more positive oxidation potential of this complex ($E_{p,a} = +0.24$ V) compared to parent [Et₄N][U(NCS)₅(bipy)₂] ($E_{p,a} = +0.22$ V).

Figure 8. Left: thin-layer cyclic voltammogram of [Et₄N][U(NCS)₅(bipy)₂] against Fc/Fc⁺ (used as the internal standard, together with cobaltocenium – Cc/Cc⁺) recorded in MeCN at 293 K, with ~0.1 M Bu₄NPF₆ as the supporting electrolyte ($\nu = 2$ mV s⁻¹); Right: IR spectral changes in the $\nu(\text{C}=\text{N})$ region accompanying the 1e⁻ reduction of [Et₄N][U(NCS)₅(bipy)₂] in MeCN.

MeCN/Bu₄NPF₆ at 293 K within an OTTLE cell. Blue spectrum: before the reduction; red spectrum: after the reduction.

Finally, we examined the redox behavior of [Et₄N]₃[UO₂(NCS)₅] in the presence of excess bipy. The reduction of the parent compound studied by TLCV and FT-IR (Figure S12) shows a cathodic wave at $E_{p,c} = -1.43$ V, and liberation of free [NCS]⁻, consistent with our earlier study. We have previously reported that the oxidation of the parent uranyl compound is difficult to study by cyclic voltammetry.³⁰ Corresponding TLCV shows irreversible oxidation at $E_{p,a} = +0.21$ V (Figure S12, right) that must be NCS-based; IR spectroelectrochemical monitoring proves the decomposition and only yellow deposits of [NCS]_x are observed in the spectroelectrochemical cell. However, in the presence of bipy, a new species with a $\nu(\text{C}\equiv\text{N})$ band at 2036 cm⁻¹ is initially generated (Figure S13, left), belonging to the uranium(IV) complex, [U(NCS)₅(bipy)₂]⁻. Under further oxidation the intermediate band decays and is replaced by the $\nu(\text{C}\equiv\text{N})$ band of [U(NCS)₈]⁴⁻ at 2048 cm⁻¹ (Figure S13), indicating that the bipy ligands dissociate (*vide supra*). It is interesting that a ligand-based oxidation triggers a metal based reduction, U(VI)→U(IV). It is well known⁴⁵ that the transient one-electron oxidized [U(V)O₂]⁺ species undergo a disproportionation reaction to form [U(IV)O₂] and [U(VI)O₂]²⁺. Table 3 summarizes the redox potentials of the three uranium thiocyanate complexes measured by TLCV.

Table 3. Formal redox potentials of the studied uranium thiocyanate complexes against ferrocene/ ferrocenium, determined by thin-layer cyclic voltammetry within an OTTLE cell.^a

Complex	$E_{p,c}/V$ (vs. Fc/Fc ⁺)	$E_{p,a}/V$ (vs. Fc/Fc ⁺)
[U(NCS) ₈] ⁴⁻	-1.38	0.24
[U(NCS) ₅ (bipy) ₂] ⁻	-0.80	0.22
[UO ₂ (NCS) ₅] ³⁻	-1.43	0.21

^a In MeCN/TBAH at 293 K.

Given that the electrochemical deoxygenation is facile, we explored chemical oxidation of [Et₄N]₃[UO₂(NCS)₅]. Reaction with organic oxidants gave no reaction, as judged by IR and UV-vis spectroscopy. Addition of CuCl₂ in MeCN afforded a brown solution; however, there were no bands in the UV-vis/NIR spectral region attributable to f-f transitions. Recrystallisation afforded three different morphologies of single crystals. X-ray crystallography showed these to be copper sulfate, [Et₄N]₂[UO₂Cl₄], and [Et₄N]₄[UO₂Cl₄][CuCl₄], **10**. Copper sulfate must have been formed from the oxidation of the [NCS]⁻ ion,⁴⁶ as the CuCl₂ was sulfate-free (via IR spectroscopy). The formation of uranyl halides corroborates the results of computational investigations showing the U–Cl bond to be more covalent than the U–NCS bond.³⁰ The structure of **10** is unremarkable and included in the Supporting Information (Figure S14, Table S3), along with luminescence (Figure S15) and vibrational (Figures S16 and S17) data.

Computational studies. In order to understand the change in reactivity between U(III) and U(IV), we turned to computational chemistry. In our previous work we benchmarked hybrid and pure DFT methods to the vibrational data of the U(IV) compound and found that the BP86 functional gave a satisfactory fit to the experimental data.³⁰ We have therefore used this to compare the bonding in [M(NCS)₈]⁵⁻, where M = Ce and U, and used QTAIM to further probe

this. It is worth reemphasizing that the 8-coordinate Ce(III) compound is not known experimentally, but used strictly as a comparison to U(III). Natural bond order (NBO) analysis finds a single bonding orbital for each M–N bond, and indicates a charge on U of just +0.96 and Ce of +0.90, much less than the formal charge of +3. Inspection of the spin densities (Figure S10) shows that there is a small amount of delocalization onto the NCS ligands in the U(III) compound, which is not observed in the Ce(III) species. QTAIM analysis show that both U(III) and Ce(III) are more ionic than the U(IV) compound, with a low ρ associated with the M–N bond and a decrease in the bond order (Table 4). Literature precedent exists where An–Cl have been described as showing enhanced covalency of the U(IV)–Cl bond versus the U(III)–Cl bond.⁴⁷ Using QTAIM⁴⁸ the ρ_{BCP} for U–Cl bond in $[\text{UCl}_6]^{n-}$ at the B3LYP functional are 0.064 for U(IV) and 0.037 for U(III), which follows the trend in our data. In this work the authors ascribe this partly to an increase in the localization of the f-orbitals with decreased oxidation state, which may indicate a decrease in the covalency of these bonds. This is an example of an energy mismatch between the metal and ligand orbitals in lower oxidation states. NBO analysis of the $[\text{U}(\text{NCS})_8]^{n-}$ gives some evidence for this, as there is a decrease in the f-orbital contribution to the bonding {U(III) 11% U: made up of s (12%), p (34%), d (39%) and f (15%); U(IV) 14% U: made up of s (12%), p (33%), d (31%) and f (24%)}. We note that the U(III)–N bond is slightly less ionic than the Ce(III)–N bond, and consistent with previous experimental results.⁵

Table 4. DFT geometry and vibrational modes using BP86 functional and selected QTAIM properties for $[\text{U}(\text{NCS})_8]^{4-}$ and the putative $[\text{M}(\text{NCS})_8]^{5-}$ compounds and experimental (exp.) data.

^a IR active bands.

The cathodic electrochemistry of $[\text{U}(\text{NCS})_5(\text{bipy})_2]^-$ and $[\text{U}(\text{NCS})_8]^{4-}$ (Table 3) shows that the LUMO is stabilized by the coordination of the bipy, suggesting its participation in the electrochemical reduction. We have reinvestigated³³ $[\text{U}(\text{NCS})_5(\text{bipy})_2]^-$ by using tighter SCF criteria within DFT calculations, and found that the LUMO is metal-based, whilst the HOMO is

based on the NCS ligands. The LUMO+3 and LUMO+4 are the lowest-lying unoccupied orbitals containing substantial contributions from $\pi^*(\text{bipy})$ combinations, as shown in Figure 9.

Figure 9. (a) HOMO; (b) LUMO; (c) LUMO+3; (d) LUMO+4 of $[\text{U}(\text{NCS})_5(\text{bipy})_2]^-$.

Conclusions

We have prepared and characterized a series of lanthanide thiocyanate complexes of the formulation $[\text{Et}_4\text{N}][\text{Ln}(\text{NCS})_4(\text{H}_2\text{O})_4]$ ($\text{Ln} = \text{Pr}, \text{Tb}, \text{Dy}, \text{Ho}, \text{Yb}$) and an unusual 8-coordinate complex $\text{Cs}_5[\text{Nd}(\text{NCS})_8]$. For thorium chemistry, we have found that full substitution of the nitrate ions in $\text{Th}(\text{NO}_3)_4$ is difficult to achieve when using the Me_4N^+ counterion. Both mono- and bis-nitrate compounds of thorium thiocyanates were characterized by X-ray diffraction. We have attempted to prepare the homoleptic U(III) compound but under all conditions failed to isolate a metal-based species. Thin-layer cyclic voltammetry and spectroelectrochemistry have shown that this is due to the facile loss of all thiocyanate ligands upon the reduction. Theoretical approaches have revealed increased ionicity of the U(III)–N bond compared to the U(IV)–N bond. The oxidation potentials of the three studied uranium thiocyanate complexes are very similar. $[\text{U}(\text{NCS})_8]^{4-}$ has the most positive oxidation potential because of the eight strongly π -donating $[\text{NCS}]^-$ ligands stabilizing the complex. The reduction potential of $[\text{U}(\text{NCS})_5(\text{bipy})_2]^-$ is much less negative than that of $[\text{U}(\text{NCS})_8]^{4-}$ because the withdrawing 2,2'-bipyridine ligands stabilize the metallic frontier molecular orbitals. Finally, the electrochemical oxidation of $[\text{UO}_2(\text{NCS})_5]^{3-}$ in the presence of bipy affords $[\text{U}(\text{NCS})_8]^{4-}$ via $[\text{U}(\text{NCS})_5(\text{bipy})_2]^-$; however, chemical oxidation with CuCl_2 affords only uranyl chlorides.

Experimental

Caution! Natural uranium and thorium were used during the course of the experimental work. As well as the radiological hazards, uranium and thorium are toxic metals and care should be taken with all manipulations. Experiments using radioactive materials were carried out using pre-set radiological safety precautions in accordance with the local rules of the Trinity College Dublin and the University of Reading.

All manipulations for actinide chemistry were carried out using standard Schlenk and glove box techniques under an atmosphere of a high purity dry argon. Lanthanide chemistry was conducted in air. Standard IR spectra were recorded on a Perkin Elmer Spectrum One spectrometer with attenuated total reflectance (ATR) accessory. Raman spectra were obtained using 785-nm excitation on a Renishaw 1000 micro-Raman system in sealed capillaries. UV-vis/NIR measurements were conducted on a Perkin Elmer Lambda 1050 spectrophotometer over the range 300–1300 nm, using fused silica cells with an optical path length of 1 cm. X-Ray data were collected on a Bruker APEX DUO (**1**, **3** and **9**) and a D8 Quest ECO (**2**, **4-8**) using Mo K α radiation ($\lambda = 0.71073 \text{ \AA}$). Each sample was mounted on a Mitegen cryoloop and data collected using a Cobra and Oxford Cryostream cryosystem. Bruker APEX software⁴⁹ was used to collect and reduce data, and determine the space group. Structures were solved using XT⁵⁰ and refined using the XL⁵¹ program within the Olex2 program.⁵² Absorption corrections were applied using SADABS 2014.⁵³ Details of the crystal data and refinements are given in Table S2. CCDC 1554951-1554959 and 1574079 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. The packing diagram shown in Figure 3 was generated using VESTA version 3.3.9.⁵⁴ Phase purity was checked by powder X-ray diffraction (Figure S5) which was carried out on a Bruker D2 Phaser.

Cyclic voltammetric measurements were conducted with a Metrohm Autolab PGSTAT302N potentiostat, in an air-tight three electrode cell connected to a Schlenk line, with a Pt microdisc (0.14 mm²) working electrode, Pt coil counter electrode, Ag coil pseudo-reference electrode; the [nBu₄N][PF₆] electrolyte was recrystallized twice from absolute ethanol and dried under vacuum

at 80 °C overnight. Controlled-potential electrolyses within the room-temperature OTTLE cell⁵⁵ were carried out using an EmStat3 (PalmSens) potentiostat. IR and UV/Vis spectral monitoring of the redox reactions was carried out with a Bruker Vertex 70v FT-IR spectrometer and a Scinco S3100 diode array spectrophotometer, respectively. The different redox steps were localized with the aid of contemporarily recorded thin-layer cyclic voltammograms. Ferrocene, decamethylferrocene (Fc*) and cobaltocenium (Cc) were used as multiple internal potential standards in this experiment. The correct position of the cathodic response of the cobaltocenium standard (-1.34 V vs Fc/Fc⁺) proves that the potential scale remained correct during the slow (2 mV s⁻¹) scan and no potential drift occurred. For cyclic voltammetry and IR spectroelectrochemistry analysis, the compounds were first characterized by IR spectroscopy (Table S2). The uranium complexes were dissolved in dry acetonitrile containing the supporting electrolyte, and checked for decomposition.

DFT geometry optimization was performed on single molecules extracted from the crystal structure, at the unrestricted BP86/def2-TZVP^{56,57} level using Turbomole⁵⁸ initially without symmetry constraints, but subsequently in D_{4d} point group. Scalar relativistic effects in uranium were included through use of effective core potentials, as defined for this basis set. Spin contamination was not significant, with values of S² within 1% of the anticipated value of 2.00. Further single-point DFT calculations were performed in Gaussian09⁵⁹ using the BP86 and B3LYP⁶⁰ functionals. The (27 s 24p 18d 14f 6 g)/[8s 7p 5d 3f 1g] all-electron ANO-RCC basis sets of DZP quality were used for uranium,⁶¹ with 6-31+G(d,p) on C, N and S.⁶² Scalar relativistic effects were included *via* the second-order Douglas-Kroll-Hess Hamiltonian.⁶³ Natural bond orbital (NBO) analysis⁶⁴ was performed using Gaussian09; Atoms-in-Molecules (AIM) analysis used AIMAll.⁶⁵ Topological analysis of the electronic density (ρ) is based upon

those points where the gradient of the density, $\nabla\rho$, vanishes.⁶⁶ In this work, we consider points where one curvature (in the inter-nuclear direction) is positive and two (perpendicular to the bond direction) are negative, termed (3, -1) or bond critical points. Properties evaluated at such points characterize the bonding interactions present. An electron density (ρ) of 0.2 a.u. or greater typically signifies a covalent bond and less than 0.1 a.u. indicates closed shell (ionic, Van der Waals, etc.). Integrated properties of atoms were checked for numerical accuracy *via* the basin integral of the Laplacian, which should vanish for properly defined atomic basins (all values 10^{-4} or less), and also by comparison of the sum of all atomic integrals with directly calculated molecular values. Integration of the overlap matrix over atomic basins can be used to derive covalent bond order, as set out by Kar and co-workers.⁶⁷

THF was distilled over potassium or Na/benzophenone whilst acetonitrile and CD_3CN were distilled over CaH_2 or P_2O_5 , and degassed immediately prior to use. $[\text{Et}_4\text{N}]_4[\text{U}(\text{NCS})_8]$,⁶⁸ $[\text{Et}_4\text{N}][\text{U}(\text{NCS})_5(\text{bipy})_2]$ ⁶⁹ and $[\text{Et}_4\text{N}]_3[\text{UO}_2(\text{NCS})_5]$ ⁷⁰ were made *via* the literature procedures. Lanthanide salts, caesium chloride, sodium thiocyanate and tetraalkylammonium chlorides were purchased from Sigma and were of reagent grade. They were used without further purification.

*Synthesis of $[\text{Et}_4\text{N}][\text{Pr}(\text{NCS})_4(\text{H}_2\text{O})_4]$ (**1**)*

$\text{PrCl}_3 \cdot 7\text{H}_2\text{O}$ (0.093 g, 0.25 mmol) was dissolved in a 15 mL of acetonitrile-water mixture (4:1, v/v). Then 5 mL aqueous solution of sodium thiocyanate (0.152 g, 2 mmol) and 10 mL acetonitrile-water mixture (4:1, v/v) containing tetraethylammonium chloride (0.017 g, 0.10 mmol) solution were added to the metal solution, stirred for 30 min and then allowed to stand for

a week. Light green colored X-ray quality single crystals of the complex **1** appeared at the bottom of the vessel. Yield = 0.103 g (72%)

Complexes **2-5** were obtained from a similar procedure to that of **1**, except that the metal salts $\text{TbCl}_3 \cdot 6\text{H}_2\text{O}$, $\text{DyCl}_3 \cdot 6\text{H}_2\text{O}$, $\text{HoCl}_3 \cdot 6\text{H}_2\text{O}$ and $\text{YbCl}_3 \cdot 6\text{H}_2\text{O}$ (0.093 g (70%), 0.094 g (62%), 0.095 g (75%) and 0.097 g (67%), respectively with each 0.25 mmol Ln halide) was used instead of praseodymium chloride.

*Synthesis of $\text{Cs}_5[\text{Nd}(\text{NCS})_8]$ (**6**)*

Hydrated NdCl_3 (0.094 g, 0.20 mmol) was dissolved in a 15 mL of acetonitrile-water mixture (4:1, v/v). Then 5 mL aqueous solution of sodium thiocyanate (0.122 g, 1.6 mmol) and 10 mL acetonitrile-water mixture (4:1, v/v) containing cesium chloride (0.168 g, 1.0 mmol) solution were added to the metal solution, stirred for 30 min and then allowed to stand. Very light green colored X-ray quality single crystals of the complex appeared at the bottom of the vessel after one week.

*Synthesis of $[\text{Me}_4\text{N}]_4[\text{Th}(\text{NCS})_7(\text{NO}_3)] \cdot 2\text{MeCN}$ (**7**)*

To a solution of $[\text{Th}(\text{NO}_3)_4] \cdot 5\text{H}_2\text{O}$ (400 mg, 0.70 mmol) in acetonitrile (30 cm^3) were added NaNCS (455 mg, 5.6 mmol) and Me_4NCl (307 mg, 2.8 mmol). After 1h of stirring at room temperature, the clear solution was filtered and the solvent was left evaporate slowly. After 1 week at room temperature, the solution deposited colorless crystals suitable for X-ray diffraction (34.7 mg, 53%).

^1H NMR (400 MHz, CD_3CN): δ 3.17 (s, 12 H, CH_3), $^{13}\text{C}\{^1\text{H}\}$ NMR (100.64 MHz, CD_3CN): δ 134.8 (NCS), 55.30 (CH_3); IR (ATR, ν/cm^{-1}): 2957 (w, C–H), 2098 (w), 2041 (s, C=N), 1480 (m), 1414 (w), 1365 (w), 1284 (m, NO_3^-), 1027 (w), 945 (m, C=S), 809 (w), 744 (w); Raman (ν/cm^{-1}): 2928, 2257, 2105 and 2061 and 2045 (C=N), 1456, 1425, 1038, 957, 827, 758; UV-vis (ϵ , $\text{dm}^3 \text{mol}^{-1} \text{cm}^{-1}$), (298 K, MeCN, $\sim 10^{-5}$ M): 344 nm (125).

Isolation of heterocycle 9

A cold (-80 °C) solution of $[\text{Et}_4\text{N}]_4[\text{UNCS}]_8$ (0.10 g, 0.8 mmol) in MeCN (30 cm^3) was added to a suspension of KC_8 (0.02 g, 5 mmol) in MeCN (20 cm^3) held at -80 °C dropwise. An immediate color change to dark red then colorless was observed. Upon warming slowly to room temperature the mixture was filtered and concentrated. Placement at -30 °C afforded a few colorless crystals suitable for X-ray diffraction.

Synthesis of $[\text{Et}_4\text{N}]_4[\text{UO}_2\text{Cl}_4][\text{CuCl}_2]$, **10**.

To a yellow solution of $[\text{Et}_4\text{N}]_3[\text{UO}_2(\text{NCS})_5]$ (200 mg, 0.21 mmol) in acetonitrile (20 cm^3), was added anhydrous CuCl_2 (56.5 mg, 0.46 mmol). After 2h of stirring at room temperature, a clear brown solution was formed and this was filtered. Slow evaporation of the solvent deposited yellow and green crystals suitable for X-ray diffraction that were separated by hand.

IR (ATR, ν/cm^{-1}): 2989 and 2950 (w, C-H), 1460 (m), 1392 (m), 1308 (w), 1184 (m), 1030 (m), 1006 (m), 916 (s, U=O), 789 (m), 637 (w), 603 (w); Raman (ν/cm^{-1}): 1459, 1060, 887, 832

(U=O), 658, 389, 255, 200; UV-vis (ϵ , $\text{dm}^3 \text{mol}^{-1} \text{cm}^{-1}$), (298 K, MeCN, 2.78 mM): 1381 nm (7.94), 914 nm (7.00), 460 nm (86.4), 310 nm (381), 256 nm (229).
