detect similarities across patients we performed dimensionality reduction using the t-distributed stochastic neighborhood embedding (t-SNE) followed by a Gaussian Mean Shift Clustering. ANOVA tests for each descriptor and each cluster were performed to find statistically significant differences. A repeated measurements model was fitted at each cluster to evaluate within-cluster trends for patients with and without toxicity (Fig. 1).

Results
Two clusters with distinct shape characteristics comprised 85% of the patients while a third cluster (15%) included outliers. Clusters remained similar when data from the entire RT course was pooled in the t-SNE classification. Significant differences between cases and controls were observed at each cluster in seven descriptors (convexity and elliptic variance along the three principal axes, and compactness). In cluster 1 (small bladder volumes) more convex and round bladders shapes were associated with higher toxicity risk, while in cluster 2 (large bladder volumes) more concave and elliptical shapes were associated with higher risk of toxicity (Fig. 2).

Late GU toxicity after RT for prostate cancer. Patient-specific changes in bladder shape might be related to the exposure of the most radiosensitive areas of the bladder to high doses.

PO-0963 A novel normalisation technique for voxel size dependent radiomic features in oesophageal cancer

Purpose or Objective
In oncology, radiomic studies hope to identify quantitative imaging features that predict survival and therapy response. To be clinically useful, features need to be robust. For 3D features that measure tumour heterogeneity, isotropic voxels are advised to ensure no directional bias [1]. Normally, PET/CT scans are not isotropic and require interpolation. The voxel size chosen is important; resampling a scan to smaller dimensions increases the number of voxels in a region of interest (ROI). An intrinsic dependency between common features and number of voxels in a ROI has been found [2]. This study evaluates methods to improve feature robustness and introduces a novel normalisation technique for voxel size dependent radiomic features in oesophageal cancer (OC).

Material and Methods
18F-FDG PET images (scanned and segmented with the same protocol) from 441 OC patients (training=353, validation=88) were included [3]. Standardised and validated [1] in-house feature extraction algorithms were used. Voxel intensities were discretised with a fixed bin width (0.5 SUV). Five selected features recommended for voxel normalisation [2] were extracted from the original scan dimension and 5 isotropic sizes. Patients were ranked based on the feature result of the original dimension. Surface models were generated on the training dataset to normalise each feature using the voxel size and feature value. A concordance correlation coefficient (CCC) was used to determine reproducibility between features extracted from the original dimension and a range of interpolated voxel sizes.

Results
Fig.1 shows development of a surface model and results for a selected feature, run length non-uniformity (RLNU). Fig.2 is a feature heatmap of the CCC results for each voxel dimension for the validation dataset. There are 3 versions of each feature; standard (CCC 0.16-0.96), voxel number normalised (CCC 0.08-0.99), and surface model normalised (CCC 0.95-0.99). Features normalised with a surface model performed the best in each case.

Conclusion
Bladder shape changes occurring during the first week of treatment show potential to predict the risk of developing...
Fig.1: Results for RLNU (training). TOP: (left) feature calculated at each voxel dimension against patient rank. (right) Feature normalised by voxel number in ROI. BOTTOM: (left) Surface model to calculate feature change. (right) Surface model shifted result.

Fig.2: CCC heatmap for each feature (validation dataset)

Conclusion
We developed, tested and validated a novel normalisation technique for voxel size dependent radiomic features. Ongoing work aims at validating the proposed approach on other imaging modalities.
