Keywords: lamina cribrosa, optic nerve head, optical coherence tomography

Running Head: Determinants of anterior laminar depth in Asian eyes

Contributor Statement: Design of study (MB, TA, CYC, CB, NGS, MJAG); Conduct of the study (TAT, YCT, MB, MEN); Collection and management of data (TAT, XW, DQN, YCT, CYC); Analysis and Interpretation of data (TAT, XW, DQN, YCT); Preparation of manuscript (TAT, XW, DQN, CB, CYC, MJAG); Review or approval of manuscript (YCT, MB, MEN, NGS, TA, CYC, CB, MJAG)

Abstract

Aim: To investigate the determinants of lamina cribrosa depth (LCD) in healthy eyes of Chinese and Indian Singaporean adults

Methods: The optic nerve head (ONH) of the right eye of 1,396 subjects (628 Chinese and 768 Indian subjects) was imaged with optical coherence tomography (OCT, Spectralis, Heidelberg, Germany). LCD was defined as the distance from the Bruch's membrane opening (LCD-BMO) or the peripapillary sclera (LCD-PPS) reference plane to the laminar surface. A linear regression model was used to evaluate the relationship between the LCD and its determinants.

Results: Both LCDs were significantly different between the two races (LCD-BMO: 421.95 (95% CI, 365.32-491.79) µm in Chinese vs 430.39 (367.46-509.81) µm in Indians, P=0.021; and LCD-PPS: 353.34 (300.98-421.45) µm in Chinese vs 376.76 (313.39-459.78) µm in Indians, P<0.001). In the multivariable regression analysis, the LCD-PPS of the whole cohort was independently associated with females (β=-31.93, P<0.001), Indians subjects (β=21.39, P=0.004) (Chinese as the reference), axial length (Axl) (β=-6.68, P=0.032), retinal nerve fibre layer thickness (RNFL) (β=0.71, P=0.019), choroidal thickness (ChT) (β=0.41, P<0.001), vertical cup disc ratio (VCDR) (β=24.42, P<0.001) and disc size (β=-60.75, P=0.001). For every 1-year older in age, the LCD-PPS was deeper on average by 1.95 µm in Chinese subjects (P=0.01) but there was no association in Indians subjects (P=0.851).

Conclusions: The LCD was influenced by age, gender, race, Axl, RNFL, ChT, VCDR and disc size. This normative LCD database may facilitate a more accurate assessment of ONH cupping using OCT in Asian populations.

INTRODUCTION

The pathologic cupping of the optic nerve head (ONH) in glaucoma occurs due to thinning of prelaminar tissues and the neuro-retinal rim, widening of the scleral canal, loss of retinal ganglion cells and their axons, and posterior deformation of the lamina cribrosa (LC).[1–3] This cupping/excavation of the ONH is assessed clinically as the vertical cup-disc ratio (VCDR)[4] and the evaluation of cupping has been augmented recently with measurements from optical coherence tomography (OCT) that provides the cross-sectional information of the ONH, including cup volume,[5,6] rim volume,[7,8] rim width,[9,10] and lamina cribrosa depth (LCD).[3,11]

The LCD defines a distance from the anterior surface of the LC to a reference plane and is a measurement of the LC deformation. A large LCD has been reported in glaucoma eyes,[12,13] but not in eyes with other optic neuropathies.[14,15] Studies have reported an increase in the LCD measurement in glaucomatous eyes that progressed, and also a decrease in LCD after intraocular pressure (IOP) lowering treatment in glaucoma patients.[16,17] Moreover, experimental glaucoma studies showed that the changes in LCD were observed prior to thinning of the retinal nerve fibre layer (RNFL)[18] or functional loss[2] of the optic nerve. Although the LCD itself or the changes in LCD was used to study the ONH cupping in glaucomatous neuropathy,[12,18–20] glaucoma progression,[2,21] after acute IOP elevations,[22,23] and after the IOP lowering surgery,[17,24,25] studies also showed that the diagnostic power of the LCD was lower in some populations.[26,27] In order to use the change in LCD efficiently in diagnosis and management of glaucoma, the normative value of the LCD should be established from a large population-based study as performed herein.

Recent studies showed that the LCD is affected by the reference plane used,[3,19] age,[21,28] gender,[26,29] race,[21,28] and axial length (Axl).[11,29] The LCD was reported to be greater in subjects of African descent than in European descent subjects,[3,28] and the former had the greater prevalence of glaucoma than the latter. Luo et al reported that Asian and Native American descent participants had shallower LCD than African descent participants, but the number of Asian subjects in the study was only 19.[3] The reports of variation in LCD of Asians are limited and studies were mostly conducted in one ethnic group. There may have been variations in measurements where study design and methodology differed. Thus, the aim of the current study was to investigate variations of the LCD with age, gender, race and other ocular variables in a population-based cohort in Singapore.

METHODS

Subject Recruitment

Subjects were recruited from the Singapore Epidemiology of Eye Diseases (SEED) study, a population-based cross-sectional study of Singapore adults aged 40 years and older. The recruitment protocol and study design of the SEED study have been reported in detail.[30] In brief, the SEED study was conducted to detect the prevalence and impact of major eye diseases among adult Singaporeans.

After 6 years, 2,661 Chinese (87.7% response rate) and 2200 Indians (75.5% response rate) subjects participated in 6-year follow-up visit (SEED2). The right eyes of 1,465 (657 Chinese and 808 Indians) consecutive subjects from SEED2 were analysed in this sub-study. Written informed consent was obtained from all participants. The study

had the approval of the SingHealth Centralized Institutional review board and adhered to the tenets of the Declaration of Helsinki. We excluded the cases with glaucoma, glaucoma suspects and other optic neuropathies based on the investigations such as visual acuity assessment, slit-lamp examination done by an ophthalmologist, intraocular pressure measurement, gonioscopy, posterior segment optical coherence tomography, and Humphrey visual field test.

Optical Coherence Tomography Imaging and Analysis

The ONH of each subject was imaged using spectral domain (SD)-OCT (Spectralis, Heidelberg Engineering, Germany). Each OCT volume scan consisted of 97 serial horizontal B-scans (30 µm distance between B-scans; 384 A-scans per B-scan; 20 B-scan averaging) that covered a rectangular area of 15° x 10° centred on the ONH.[22,23] Raw SD-OCT images were post-processed and enhanced using adaptive compensation to reduce blood vessel shadows and to improve the visibility of the LC and the peripapillary sclera (PPS).[31] For each eye, post-processed OCT volumes were resampled with reference to the subject-specific fovea-ONH axis (**Figure 1**) and the central B-scan was chosen for analysis using custom-written MATLAB (MathWorks Inc., Natick, MA) algorithms.

Bruch's membrane opening (BMO) was defined as the end point of the Bruch's membrane (BM) layer (or the retinal pigment epithelium/BM complex) on either side of the ONH. The PPS was defined by a sharp increase in axial signal intensity extending laterally from anterior sclera to the LC through the LC insertion points.[32]

The two BMO points were manually marked and a peripapillary ring was automatically drawn from the centre of the BMO with an inner and outer radius of 1,200 µm and 1,800 µm respectively. The PPS surface within the peripapillary ring and the anterior surface of the LC were also manually delineated. (**Figure 1**)

The line joining two BMO points was defined as the BMO reference plane[10] (**Figure 1A**) and the line joining the outermost points of the peripapillary ring was defined as the PPS reference plane. (**Figure 1B**) The PPS reference plane was adopted to avoid irregularities and poor visualization at the anterior sclera opening.[19,28]

Using the aforementioned delineations, our custom algorithms derived the following parameters.[22,23]

1. *Lamina Cribrosa Depth (LCD)*

The LCD was defined as the perpendicular distance from anterior LC surface to the reference planes of BMO (**Figure 1A**) and PPS (**Figure 1B**). All LCD values in the region of central one-third of the length of the BMO were averaged and reported as the mean LCD from each reference plane.

2. Choroidal thickness (ChT)

The ChT was defined as the thickness between the BM and PPS boundary within the peripapillary ring and represented as the mean thickness in µm. (**Figure 1**)

3. Disc size

The disc size was defined as the distance between two BMO points and represented as “L” (BMO length) in **Figure 1**.

Validation of image grading

Reproducibility of the segmentation of the images was evaluated by performing intra- and inter-observer reproducibility tests on the measurements of the LCD-BMO and LCD-PPS. A subset of 40 images was selected using a random sampling method and delineated by the first observer. The second observer (masked to the results of the first grading) delineated the same set of images in a random order for the inter-observer reproducibility. The first observer repeated the image segmentation in a random order after a 2-week interval for intra-observer reproducibility.

Statistical Analysis

Statistical analyses were performed using R software version 3.22 (R Development Core Team (2008), http://www.R-project.org). Continuous variables were described as the median, and interquartile range (25^{th}-75^{th}). We used the independent T test to compare the differences in the distribution of continuous variables of two samples and used the Pearson correlation coefficient (r) to assess the association between the LCD and other determinants. We employed linear regression models to assess the relationship of LCD-BMO or LCD-PPS with its determinants after adjusting for potential confounders (that were significant in univariable analysis). We used Bland Altman analysis of MedCalc® (Windows v14.12.0, Mariakerke, Belgium) to compare the intra- and inter-observer reproducibility of segmentation of our customized algorithms. Statistical significance was set at $P<0.05$.

RESULTS

Demographic and Clinical Characteristics

Of the 1,465 consecutively recruited subjects, right eyes of 1,396 participants (628 Chinese and 768 Indians) were included in the final analysis after excluding 69 (29 Chinese and 40 Indians, 4.71%) due to poor visibility of the anterior sclera. **Table 1** shows the demographic and clinical characteristics of the study subjects. The median (IQR) of age of Chinese was comparable to that of Indians (58.73 vs 58.38 years, P=0.318). The weight, body mass index, diastolic blood pressure and mean arterial pressure were higher in Indians than Chinese subjects (**Table 1**). Indians subjects also had higher IOP, lower central corneal thickness (CCT), shorter Axl, lower RNFL thickness, greater VCDR and relatively smaller disc size than Chinese subjects in this study. The median (IQR) of LCD-BMO was 426.07 (365.82-00.04) µm and LCD-PPS was 365.89 (307.92-440.41) µm ; and both LCDs were significantly different between the two races (LCD-BMO: 421.95 (365.32-491.79) µm in Chinese vs 430.39 (367.46-509.81) µm in Indians, P=0.021; and LCD-PPS: 353.34 (300.98-421.45) µm in Chinese vs 376.76 (313.39-459.78) µm in Indians, P<0.001).

Intra- and Inter-observer reproducibility of image grading

Bland-Altman analysis of LCD-BMO measurement showed that the mean difference was 6.88 (95% confidence interval (CI), -3.057, 16.817) for intra-observer reproducibility and the mean difference was 7.923 (95%CI, -1.665, 17.511) for inter-observer reproducibility. The limits of agreement (LOA) for intra-observer reproducibility was from -54.019 (95%CI, -71.144, -36.894) to 67.78 (95%CI, 50.654, 84.905). The

LOA for inter-observer reproducibility was from -50.837 (95%CI, -67.36, -34.313) to 66.683 (95%CI, 50.159, 83.207). (online supplementary **Figure S1A and C**)

Bland-Altman analysis of LCD-PPS measurements showed that the mean difference was 2.899 (95%CI, -5.341, 11.14) for intra-observer reproducibility and the mean difference was 2.883 (95%CI, -4.555, 10.32) for inter-observer reproducibility. The LOA for intra-observer reproducibility was from -47.602 (95%CI, -61.804, -33.401) to 53.401 (95%CI, 39.199, 67.602). The LOA for inter-observer reproducibility was from -42.7 (95%CI, -55.519, -29.882) to 48.465 (95%CI, 35.647, 61.284). (online supplementary **Figure 1B and D**)

Association of LCD with clinical/ocular parameters

The LCD-BMO was associated with age, gender, Axl, spherical refractive error, VCDR, RNFL, disc size and ChT, while the LCD-PPS was associated with gender, Axl, spherical refractive error, VCDR, disc size and ChT. (online supplementary **Table S1**) Even though they showed statistical significance, these associations were weak (r value ranging from 0.068 to 0.193) with the exception of ChT. The association of ChT with the LCD-BMO was fair (r=0.489) but with the LCD-PPS was poor (r=0.228). Online supplementary **Figure S2** shows the histograms of LCD-BMO and LCD-PPS in the whole cohort as well as racial groups separately. The LCD from both reference planes showed a right-skewed curve (exponentially-modified Gaussian distribution) by the Shapiro-Wilk test (all P<0.001).

Table 2 shows the relationships of LCD for the whole cohort (n=1,396) with clinical/ocular variables. The multivariable regression analysis showed that the LCD-

BMO on average was shallower by 33.13 µm in females, was increased by 0.78 µm for every 1 µm thicker RNFL, was increased by 0.91 µm for every 1 µm thicker ChT and was increased by 19.01 µm for every 0.1 ratio increase of VCDR, after adjusting for age, race, and Axl. The LCD-PPS of the whole cohort was also shallower on average by 31.93 µm in females, was deeper by 21.39 µm in Indians when compared with Chinese, was shallower by 6.68 µm for every 1 mm increase in Axl, was increased by 0.71 µm for every 1 µm thicker RNFL, was deeper by 0.41 µm for every 1 µm increase in ChT, was increased by 24.42 µm for every 0.1 ratio increase of VCDR and was shallower by 60.75 µm for every 1 mm greater in disc size, after adjusting to age. (**Table 2**)

The relationships of LCD-BMO with its determinants are shown in online supplementary **Table S2**. The LCD-BMO was associated with age in univariable analysis (Chinese: β=-1.42, P=0.006, Indians: β=-1.34, P=0.007) but the association was lost when adjusting for the confounders of gender, race, axl, RNFL, ChT, VCDR and disc size. The multivariable regression analysis showed that the LCD-BMO was associated with RNFL and ChT in Chinese subjects; and it was associated with gender, RNFL, ChT and VCDR in Indians subjects, after adjusting for age and Axl.

Table 3 shows the relationships of LCD-PPS with its determinants. The multivariable regression analysis showed that the LCD-PPS in Chinese subjects was associated with age and ChT while that in Indians subjects was associated with gender, Axl, RNFL, ChT, VCDR and disc size, after adjusting for the cofounders. Similarly, after adjusting for the confounders, the association between the LCD-PPS and age achieved significance (P=0.009) in Chinese subjects, but not in Indians subjects (P=1).

Figure 2 shows a schematic, illustrating racial differences in ocular parameters between Chinese and Indians subjects.

DISCUSSION

In this population-based cohort, we studied anterior laminar depth of the ONH in Chinese and Indian adults in Singapore. The median (IQR) of LCD-BMO was 426.07 (365.82-500.04) µm and LCD-PPS was 365.89 (307.92-440.41) µm; and LCD of Indians was significantly greater than that of Chinese adults. The laminar depth was shallower in females, shallower in eyes with greater Axl, deeper in eyes with thicker RNFL, deeper in eyes with thicker choroid, deeper with greater VCDR and shallower in eyes with large disc size. The LCD from the BMO reference plane was fairly influenced by choroidal thickness, but that from the anterior sclera plane was not. To evaluate the health of the optic nerve, accurate assessment of ONH cupping is fundamental for screening, diagnosis and monitoring of glaucoma. In vivo imaging of the ONH using OCT provides a more objective and comprehensive way to assess cupping using the laminar depth; however, a consistent anatomical landmark for the reference plane, a normative database with a large sample size, and factors influencing the measurements are required. This paper reports the results from a large dataset of the two largest ethnic groups in Asia and provides a population-based normative value that has no selection bias and generalizability.

Normative value of anterior lamina cribrosa depth and racial variation

In this cohort, we found that the LCD was significantly different between the two races either using BMO or PPS as the reference plane. A multicenter study has

reported the LCD-BMO was 402±91 µm and LCD-PPS was 332±96 µm in 362 normal subjects, but their results could not represent the normative values for the Asian population because only 19 Asian subjects were involved in the study.[3] A study from Korea also showed similar findings (LCD-BMO = 402.06±101.46 µm) in 300 healthy eyes of 150 Korean subjects.[29] Since ethnic differences exist in the distribution of laminar depth, this disparity should be considered based on their respective ethnic-specific normative values while assessing the extent of ONH cupping in the clinic, or while designing clinical trials and research studies.

Laminar depth and choroid

Vianna et al. reported that the ChT influenced the LCD when the BMO plane was used; but the measurement from anterior sclera was not or less influenced by the choroid. Our results confirmed these associations in a large and population-based data. Morphologically, the choroidal layer is located between the reference plane of BMO and the anterior lamina surface so its thickness could be a part of the LCD and was influencing the measurement of the LCD-BMO.[19] Importantly, thinning of the choroid layers due to many factors such as ageing, high myopia, and uncontrolled diabetes and variations of choroid in racial groups have to be considered when the LCD-BMO is used.

Variation of lamina cribrosa depth with vertical cup-disc ratio and disc size

The VCDR was highly associated with the LCDs in this study suggesting that the LC was deeper in the eyes with a greater VCDR. Our results are consistent with the study conducted by Jung et al.[33] They reported that the LC was more deeply located

within the ONH of the eye with a higher VCDR when compared with the fellow eye with a lower VCDR.

Disc size was significantly different between Chinese and Indians in this study, but the difference was relatively small. We found that the LCD from the PPS reference plane was shallower in eyes with large discs. Luo et al. also found that the LCD was shallower in eyes with a large disc.[3] Large discs were thought to be susceptible to glaucoma especially in African populations.[34] However, other studies also reported that the disc size was not associated with the glaucoma susceptibility.[35] From a mechanical point of view, a large disc size may be associated with a larger total area of the LC, and thus more deformations when IOP increases.[34]

Variation of laminar depth with gender, axial length and age

We found that the LCD was shallower in females and in eyes with greater Axl especially in subjects of Indian descent. Our results are in concordance with previous studies which reported that gender and Axl influence LCD measurement.[3,29] It is unknown why the LCD was shallower in females, however, the disc area was larger in male than in female subjects.[36] A larger disc area may have a bigger eye ball and a deeper cup, but a longer eye ball was associated with shallower cup in the current study.

The LCD relative to the BMO plane decreased with age in the univariable analysis of our study and other studies;[3,21,28] but this association was lost after adjusting for the ChT in our study. (**Table 2**) After adjusting for the confounders, the LCD relative to the PPS plane in Chinese adults was deeper with increasing age, but this relationship was not found in the Indian adult cohort. The posterior migration of

BMO due to age-related choroidal thinning may influence the LCD from the BMO plane;[19,37] and aged-related remodelling of sclera such as PPS bowing posteriorly may also affect the measurement from the PPS plane. Investigation of age-related LC changes in a large ethnic-specific sample may facilitate or optimize the detection of local ONH changes in eyes at risk of glaucoma and the estimation of disease progression.

There are several limitations in the current work. First, only the central B-scan was used to measure the LCD. However the centre of the ONH has been shown to exhibit the maximum LC displacement following short-term IOP elevation[38] and, moreover, the central part provides a consistent measurement without the variable visibility of the peripheral lamina - especially under the area of blood vessel shadows nasally. Second, we excluded 4.71% of the sample due to limited visibility of LC and PPS even though we used customized algorithms to enhance the quality of the B-scans. Third, we used only two reference planes (BMO and PPS) in the current study, as in the previous studies.[19,28] Four reference planes (BMO, BM, scleral canal opening and PPS) had provisionally been proposed.[3] However, both the BM reference plane and the BMO plane are influenced by choroid; and the scleral opening plane was not chosen due to limited visibility.

In summary, the current study found that the laminar depth was shallower in females, in eyes with greater axial length and in eyes with larger disc size. The LC was deeper in Indians than in Chinese subjects, in eyes with thick retinal nerve fibre layers, in eyes with thicker choroids and in eyes with greater VCDR. Understanding the factors influencing the measurement of the LCD and its normative value in Asian eyes will

facilitate more accurate assessment of optic nerve cupping for diagnosis and monitoring of glaucoma in Asian populations using SD-OCT.

Table 1. Demographic and ocular characteristics of the 1,396 study subjects

Variables	**Total (n =1396)**	**Chinese (n=628)**	**Indians (n=768)**	
	Median (IQR)	Median (IQR)	Median (IQR)	P value
Age, year	58.52 (53.94-65.03)	58.73 (54.18-64.99)	58.38 (53.69-65.04)	0.318
Gender, female	711 (50.97%)	332 (52.87%)	379 (49.41%)	0.219
Height (cm)	162.5 (156.5-169)	162 (156.57-168.62)	162.7 (156.5-169)	0.932
Weight (kg)	65.8 (57.9-74.53)	62.45 (55.29-69.5)	68.75 (61-77.28)	**<0.001**
Body mass index (kg/m2)	24.58 (22.37-27.49)	23.36 (21.37-25.85)	26.02 (23.39-28.53)	**<0.001**
Systolic blood pressure (mmHg)	134 (122-146.5)	134 (121-146.62)	133.5 (123-145.5)	0.673
Diastolic blood pressure (mmHg)	75.5 (70-82.5)	74.5 (68.5-81.5)	76.83 (71-83.5)	**<0.001**
Mean arterial pressure (mmHg)	95.17 (88.17-102.75)	94.67 (87.29-102.33)	95.69 (89.21-103.33)	**0.013**
Best corrected visual acuity, unit	0.1 (0-0.2)	0.1 (0.02-0.2)	0.1 (0-0.2)	0.579
Spherical equivalent, dioptre	0.2 (-0.9-1.12)	-0.16 (-1.6-0.75)	0.45 (-0.5-1.44)	**<0.001**
Intraocular pressure, mmHg	15 (13-16)	14 (12-16)	15 (14-17)	**<0.001**
Ocular perfusion pressure, mmHg	53.78 (49.11-58.78)	53.39 (48.75-58.78)	53.89 (49.33-58.67)	0.181
Central corneal thickness, µm	548 (526-570)	554 (532.25-575)	542 (522-564)	**<0.001**
Axial length, mm	23.53 (22.96-24.28)	23.81 (23.22-24.68)	23.35 (22.78-23.96)	**<0.001**
Vertical cup-disc ratio	0.35 (0.31-0.44)	0.33 (0.31-0.39)	0.38 (0.31-0.47)	**<0.001**
Retinal nerve fibre layer, µm	91.26 (84.84-98.94)	98 (91.78-104.49)	88 (81-94)	**<0.001**
Choroidal thickness, µm	153.52 (125.19-192.29)	147.72 (117.26-190.8)	158.63 (130.5-193.64)	0.131
Disc size, mm	1.64 (1.52-1.77)	1.65 (1.54-1.78)	1.64 (1.51-1.76)	**0.047**
LCD-BMO	426.07 (365.82-500.04)	421.95 (365.32-491.79)	430.39 (367.46-509.81)	**0.021**
LCD-PPS	365.89 (307.92-440.41)	353.34 (300.98-421.45)	376.76 (313.39-459.78)	**<0.001**

LCD-BMO is anterior lamina cribrosa depth from the reference plane of Bruch's membrane opening; LCD-PPS is anterior lamina cribrosa depth from the reference plane of anterior sclera; IQR is interquartile (25^{th}-75^{th}) range. A bold font denotes a statistically significant difference with p value less than 0.05.
