Purpose:

• Functional movement assessment is essential in screening individuals for risk of injury and planning physiotherapy (Fox et al. 2017). The Landing Error Scoring System (LESS) is a valid and reliable paper-based tool used in assessing the risk of knee injury, which requires evaluating multiple joints across two planes using two video cameras, whilst participants land from a jump. The LESS involves 17 items concern detecting any faulty movements (errors), then counting these errors as an overall score of the LESS (Padua et al. 2009).

• This is seldom used in physiotherapy clinics and sport fields because of the space required to place cameras, lack of obtaining related clinical movement outcomes objectively, and the privacy of the subjects.

• Wearable sensors which quantify accurate clinical movement outcomes and generate a 3D avatar recording could be a potential tool for movement analysis in physiotherapy (Al-Amri et al. 2018).

The aim of this work was to compare avatar to video recording in assessing jump-landing movements.

Method:

• Eighteen healthy subjects (age: 28.11±3.34 years; height: 170±7.58 cm; and mass: 72.01±17.27 Kg) performed jump-landing movements under two conditions.

• The first condition was at their comfortable normal technique; whilst the second involved compensation by landing with knee valgus.

• Two video cameras and 17 wearable sensors placed on the upper and lower body were used to capture the movements.

• The video and avatar recordings were given a unique name (three digits number) and then two raters scored the LESS without knowing which recording belongs to the other.

• The Intraclass correlation coefficient (ICC) and Bland and Altman plots were used.

Result:

• The validity of avatar recording against video recording for rater 1 showed moderate to strong validity (ICC= 0.47 and 0.76) for both normal and compensate jump-landing movement, respectively. Whilst rater 2 showed moderate to fair validity (ICC= 0.42 and 0.29) for both the normal and compensate jump-landing movement, respectively.

• All Bland and Altman plots showed that the overall scores are scattered around the mean within 95% limit of agreement.

Conclusion:

• The results indicate that avatar recording is comparable to video recording in assessing individual’s movement like jump-landing. However, it seems that both raters scored LESS more accurate using avatar recording than video recording during the compensate movement. Together this suggests that avatar recording could be a promising tool to be used in assessing jump-landing movement.
