Running title: Novel vasocontractile role of P2Y\textsubscript{14} receptor
**Background and purpose:** The P2Y₁₄ receptor is the newest member of the P2Y receptor family; it is G<sub>10</sub> protein-coupled and is activated by UDP and selectively by UDP-glucose and MRS2690 (7-10 fold more potent than UDP-glucose). This study investigated whether the P2Y₁₄ receptor is functionally expressed in porcine isolated pancreatic arteries.

**Experimental approach:** Pancreatic arteries were prepared for isometric tension recording and UDP-glucose, UDP and MRS2690 applied cumulatively after preconstriction with U46619, a thromboxane A₂ mimetic. Levels of phosphorylated MLC2 were assessed with Western blotting. Levels of cAMP were assessed using a competitive enzyme immunoassay kit.

**Key results:** Concentration-dependent contraction with a rank order of potency of MRS2690 (10-fold) > UDP-glucose ≥ UDP was observed; contraction was reduced by PPTN, a selective antagonist of P2Y₁₄ receptor, which did not affect the response to UTP. Contraction to UDP-glucose was not affected by MRS2578, a P2Y₆ receptor selective antagonist. In the presence of U46619 and forskolin, which increases cAMP levels, contraction to UDP-glucose was enhanced. In addition, UDP-glucose and MRS2690 inhibited forskolin-stimulated cAMP levels. Removal of the endothelium and inhibition of endothelium-derived contractile agents (thromboxane A₂, prostaglandin F₂α and endothelin-1) inhibited contractions. Y-27632, nifedipine and thapsigargin also reduced contraction to the agonists. UDP-glucose and MRS2690 increased MLC2 phosphorylation, which was blocked by PPTN.

**Conclusions and implications:** These data identify a novel vasocontractile role of P2Y₁₄ receptors in porcine pancreatic arteries. P2Y₁₄-mediated contraction involves cAMP-dependent mechanisms, an elevation of Ca²⁺ levels, activation of RhoA/ROCK signalling, and MLC2 in porcine pancreatic arteries. It also involves a release of thromboxane A₂, prostaglandin F₂α and endothelin-1.
Keywords: UDP-glucose, UDP, MRS2690, P2Y\textsubscript{14} receptor, vasoconstriction, endothelium.

Abbreviations: ATP, Adenosine-5'-triphosphate; HEK, human embryonic kidney; cAMP, 3'-5'-cyclic adenosine monophosphate; DAG, diacylglycerol; IP\textsubscript{3}, inositol 1,4,5-triphosphate; MLC2, myosin light chain 2; NDGA, nordihydroguaiaretic acid; PBS, phosphate-buffered saline; PGF\textsubscript{2α}, prostaglandin F\textsubscript{2α}; PKC, protein kinase C; PPADS, pyridoxal phosphate-6-azophenyl-2',4'-disulphonate; PPTN, 4-(4-(Piperidin-4-yl)phenyl)-7-(4-(trifluoromethyl)phenyl)-2-napthoic acid; RhoA, ras homolog gene family member A; ROCK, Rho-associated protein kinase; SNP, sodium nitroprusside; UDP, uridine diphosphate; UDP-glucose, uridine diphosphate glucose; UTP, uridine-5'-triphosphate.
**Introduction**

P2Y Receptors are members of the superfamily of G-protein coupled receptors (GPCRs); they are responsive to purine and pyrimidine nucleotides and nucleotide sugars (ADP, ATP, UTP, UDP and UDP-glucose). Eight mammalian subtypes of P2Y receptors have been identified: P2Y\textsubscript{1}, P2Y\textsubscript{2}, P2Y\textsubscript{4}, P2Y\textsubscript{6}, P2Y\textsubscript{11}, P2Y\textsubscript{12}, P2Y\textsubscript{13} and P2Y\textsubscript{14} receptors (Abbracchio *et al.*, 2006). The P2Y\textsubscript{14} receptor was the most recently identified (Chambers *et al.*, 2000). In contrast to other P2Y receptors, P2Y\textsubscript{14} receptors are activated by nucleotide sugars such as UDP-glucose, in addition to UDP-galactose and UDP-glucuronic acid which are less potent than UDP-glucose (Abbracchio *et al.*, 2003; Fricks *et al.*, 2008; Harden *et al.*, 2010). They are also activated by UDP and MRS2690 (2-thiouridine-5′-diphosphoglucose), which is more selective at P2Y\textsubscript{14} receptors and 7-10 fold more potent than UDP-glucose (Carter *et al.*, 2009; Jacobson *et al.*, 2009; Gao *et al.*, 2010). The P2Y\textsubscript{14} receptor is involved in G\textsubscript{i}-protein-mediated signalling, leading to the inhibition of adenylyl cyclase activity and, accordingly, is pertussis toxin-sensitive (Jacobson *et al.*, 2009). G\textsubscript{i}-protein-derived G\textsubscript{βγ}-dimers can initiate phospholipase C\textsubscript{β} (PLC\textsubscript{β}) signalling pathways, which lead to the stimulation of diacylglycerol (DAG) and inositol 1,4,5-triphosphate (IP\textsubscript{3}) and subsequent activation of RhoA/ROCK signalling, protein kinase C (PKC) and myosin light chain (MLC) kinase, besides elevation of the intracellular calcium level (Amano *et al.*, 1996; Hartshorne & Gorecka, 2011; Sesma *et al.*, 2012).

Pyridoxalphosphate-6-azophenyl-2′,4′-disulphonate (PPADS) and suramin are non-selective antagonists at most of the P2Y receptors, but some P2Y receptors are insensitive to these antagonists (Chootip *et al.*, 2005). There is currently no report of antagonist sensitivity of P2Y\textsubscript{14}
receptors for suramin and PPADS. Recently, a novel antagonist at P2Y₁₄ receptors was identified; this antagonist, named 4-(4-(piperidin-4-yl)phenyl)-7-(4-(trifluoromethyl)phenyl)-2-naphthoic acid (PPTN) (Barrett et al., 2013), was characterised in HEK cells through its ability to inhibit UDP-glucose-stimulated Ca²⁺ mobilization (Robichaud et al., 2011). In addition, it showed good affinity for the P2Y₁₄ receptor (Kᵢ = 1.9 nM in a chimpanzee P2Y₁₄ binding assay) (Robichaud et al., 2011). When it was studied in human C6 glioma cells, PPTN showed selectivity for P2Y₁₄ receptors with a Kᵦ of 434 pM, with no agonist or antagonist affinity at P2Y₁, P2Y₂, P2Y₄, P2Y₆, P2Y₁₁, P2Y₁₂ or P2Y₁₃ receptors (Barrett et al., 2013).

P2Y₁₄ receptor mRNA and protein have a varied expression in the body; they have been found in the spleen, placenta, lung, heart, adipose tissue, gastrointestinal smooth muscle, endothelial cells, and immune cells (Chambers et al., 2000; Scrivens & Dickenson, 2005; Umapathy et al., 2010). Relatively little is known, however, about the functional expression of the P2Y₁₄ receptor; best characterised is its role in regulation of the immune system, as a number of studies have described an involvement of P2Y₁₄ receptors in modulation of the function of human neutrophils and T-lymphocytes, and in secretion of the pro-inflammatory cytokine IL-8 in airway epithelial cells (Scrivens & Dickenson, 2005, 2006; Jacobson et al., 2009). UDP-glucose can be released in a constitutive manner, and during shear stress, to act as an extracellular signalling molecule (Lazarowski et al., 2003); its release from multiple cell types suggests potentially broad role(s) of the P2Y₁₄ receptor.

Although the exact mechanisms remain to be established, an increase in pancreatic endocrine cell activity during hormone secretion corresponds with an increase in blood flow, to meet metabolic demand. Thus, alterations in blood flow can influence pancreatic function. The role of exogenous purine and pyrimidine di- and triphosphate nucleotides in controlling the
functions of endocrine and exocrine components of the pancreas are well described (Novak, 2008; Burnstock & Novak, 2012). Within the pancreatic vasculature, P2X receptors were suggested to mediate vasoconstriction, and P2Y receptors vasodilatation, in response to ATP (Hillaire-Buys et al., 1991). P2X1, P2Y2, P2Y4 and P2Y6 receptors, with different sensitivities to ATP, UDP and UTP, mediate vasoconstriction in a number of blood vessels (Ralevic and Burnstock, 1998), and there is some evidence for a vasocontractile function of the P2Y12 receptor (Wihlborg et al., 2004; Högberg et al., 2010). In the current study, we describe the pharmacological characterisation of P2Y14 receptor-mediated contractile responses of porcine isolated pancreatic artery preparations. A preliminary account of some of these data has previously been presented to the British Pharmacological Society (Alsaqati et al., 2010).

**Materials and methods**

**Tissue Preparation**

Pancreases from pigs (either sex, age less than 6 mo, wt ~50 kg) was obtained on ice from a local abattoir (G Wood & Sons Ltd, Mansfield). A crude dissection was conducted to isolate the pancreatic arteries (greater pancreatic artery) which were located in the body of the pancreas. The vessels were dissected out and placed in Krebs’-Henseleit buffer containing 2% (w/v) Ficoll (type 70) and refrigerated overnight at 4ºC. The next day, fine dissection was performed, and the arteries cut into rings of 0.5 cm in length and suspended in Krebs’-Henseleit buffer (gassed, 95% O₂, 5% CO₂).

The endothelium of some arteries was removed by gently rubbing their innermost surface with forceps before attaching it to the setup (Rayment et al., 2007a). Successful removal of endothelium was tested using substance P (10 nM). Endothelium-denuded arteries relaxed in response to substance P to less than 10% of the U46619 (11α,9α-epoxymethano-PGH₂) induced
contraction, while in endothelium-intact arteries the relaxation to substance P was \(36\% \pm 8\) (n=7, data not shown).

**Responses in the porcine isolated pancreatic artery**

Arterial rings were mounted onto wires in tissue baths (20 ml) containing warm (37°C), oxygenated Krebs’-Henseleit solution and were connected via isometric force transducers (ADInstruments, Sydney, Australia), to a PC running the computer program LabChart (ADInstruments, Sydney, Australia). Rings were put under tension (15 g) and allowed to equilibrate for 60 min before assessing viability with two challenges of 75 mM potassium chloride (KCl). The tissues were then allowed to equilibrate for 60 min, after which U46619 (10 - 100 nM), a thromboxane A\(_2\) mimetic, was used to contract the tissues to between 40-80% of the second KCl response. This ensured that if there was a vasodilator component to the response, for example due to activation of multiple P2 receptor subtypes, this could be detected. Once an appropriate level of U46619 response had been achieved, cumulative addition of UDP-glucose, UDP or MRS2690 were applied. Antagonists or inhibitors were applied 10 min prior to the addition of U46619, allowing incubation with the tissues for a minimum of 30 min prior to the application of agonists. Desensitisation of the contraction to UDP-glucose was generated by exposing the arteries to UDP or UDP-glucose 10 min prior the addition of U46619. An exception to preconstriction with U46619, were experiments with L-655,240 (1-[(4-Chlorophenyl)methyl]-5-fluoro-α,α,3-trimethyl-1H-indole-2-propanoic acid), in which arteries were preconstricted with endothelin-1. In experiments using dimethyl sulfoxide (DMSO) as the solvent (see reagents and drugs section), DMSO was added to the arteries (vehicle control).
**Effect of forskolin on subsequent UDP-glucose or UTP responses**

Tissues were exposed to U46619 (10 - 100 nM) and relaxed with forskolin (1 µM), involving elevation of cAMP, back to the baseline; cumulative concentration-response curves were then constructed for UDP-glucose (1 µM – 1 mM) or UTP (10 µM – 1 mM). Responses to UDP-glucose or UTP obtained under these conditions were compared to control responses in which drugs were added at basal tone without exposing to either U46619 or forskolin. The tissue was allowed to recover for 20 min before a concentration-response curve to UDP-glucose or UTP was constructed.

**Western blotting**

Segments of porcine pancreatic arteries were set up in the organ baths and tensioned to 15 g, then left for approximately 60 min to reach a new baseline of resting tension. Tissues were incubated with 100 µM UDP-glucose for 30, 60, 120, 180, 240 and 300 s. In addition, in other experiments, the tissues were incubated with UDP-glucose (100 µM) or MRS2690 (10 µM) for 30 s in the presence or absence of PPTN. Segments were quickly removed from the organ baths and immediately frozen on dry ice. Control tissues were not exposed to any compound (basal conditions). Segments were then homogenised in lysis buffer (20 mM Tris, 1 mM EGTA, 0.1% (v/v) Triton X100, 1 mM NaF, 10 mM beta glycerophosphate, pH 7.6), containing protease inhibitor cocktail tablets, EDTA free. Samples with solubilisation buffer 6xSB: (24% (w/v) sodium dodecyl sulphate, 30% (v/v) glycerol, 5% (v/v) beta mercaptoethanol, 2.5% (v/v) bromophenol blue, 1.5M Tris HCl, pH 6.8 ) were heated at 95°C for 5 min. Subsequently, electrophoresis was carried out on 4-20% Tri-Glycine (PAGE) Gold Precast Gels (Bio-Rad, Hercules, CA, U.S.A.), 15 µg protein per lane. Samples were transferred to nitrocellulose membranes. Next, blots were incubated in blocking solution (5% (w/v) powdered milk in Tris-buffered saline containing 0.1% (v/v) Tween 20) for 60 min, at room temperature. Blots were
incubated overnight at 4°C with primary antibody against phosphorylated myosin light chain kinase 2 (MLC2, 1:500) or total (MLC2, 1:1000) diluted in blocking solution. After washing in Tris buffered saline containing 0.1% (v/v) Tween 20, the blots were incubated with an appropriate IRDye®-conjugated secondary antibody (LI-COR). Proteins were visualised using the Licor/Odyssey infrared imaging system (Biosciences, Biotechnology). Bands were analyzed by densitometry using the Odyssey application software and expressed as phosphorylated MLC2 normalised to total MLC2. For investigating the existence of P2Y_{14} receptor in pancreatic arteries, untreated samples were homogenised and examined as explained above.

**cAMP measurement in porcine pancreatic arteries**

Pancreatic artery rings were stimulated with 75 mM KCl followed by U46619 (10 nM) and forskolin (1 μM), and then the arteries were challenged for 3 min with UDP-glucose (1 mM), MRS2690 (10 μM), UTP (1 mM) or distilled water (control group). Pancreatic rings were collected and immediately frozen on dry ice and then stored in vials at -80°C until their study. The tissues were homogenised in 5% (w/v) trichloroacetic acid (TCA) in water with a borosilicate glass, homogeniser, and then centrifuged for 10 min at 1500 g. TCA was extracted from the supernatant samples using water-saturated ether, and evaporated for 5 min to remove the residual ether from the aqueous fractions. Samples were diluted (1:2) in ether-extracted 5% (w/v) TCA. cAMP concentration was measured using a competitive enzyme immunoassay kit (Cayman Chemical Co., Ann Arbor, MI). The working range of the cAMP assay was 0.1–1000 pmol/ml. cAMP concentration was expressed as a percentage of forskolin-induced [cAMP] elevation.
Reagents and Drugs

Krebs’-Henseleit buffer was composed of the following (mM): NaCl 118, KCl 4.8, CaCl$_2$.H$_2$O 1.3, NaHCO$_3$ 25.0, KH$_2$PO$_4$ 1.2, MgSO$_4$.7H$_2$O 1.2 and glucose 11.1. Suramin, NDGA, nifedipine, thapsigargin, UTP, U46619, sodium nitroprusside (SNP), zafirlukast, BQ788 (N-cis-2,6-dimethylpiperidinocarbonyl-L-gmethylleucyl-D-1-methoxycarbonyl-D-norleucine), UDP-glucose and UDP were purchased from Sigma (Poole, Dorset, UK), while DUP 697, MRS2578 (N,N''-1,4-butanediyl bis(N''-[3-isothiocynatophenyl]) thiourea), PPADS and substance P, MRS2690, L-655,240, endothelin-1, BQ123 (cyc(DTrp-DAsp-Pro-D-Val-Leu)), Y-27632 (trans-4-[(1R)-1-aminoethyl]-N-4-pyridinyl-cyclohexane carboxamide) and forskolin were from Tocris Biosciences Ltd. (Bristol, UK). PPTN, a selective high affinity antagonist of P2Y$_{14}$ receptor, was kindly gifted from Merck Frosst Centre for Therapeutic Research. Primary antibodies for Western blotting were purchased from Cell Signalling Technology for phosphorylated MLC2 antibody, (cat no. 3674S) and total MLC2 antibody, (cat no. 3672). Cyclic AMP EIA kit (cat No. 581001) was purchased from Cayman Chemical Company, (Ann Arbor, MI). U46619 was dissolved in ethanol at 10 mM stock concentration. DUP 697, PPTN, BQ788, MRS2578, L-655,240, nifedipine, thapsigargin, zafirlukast and forskolin were dissolved in DMSO. All other drugs were dissolved in distilled water. All reagents and drugs nomenclature conformed to BJP’s Guide to Receptors and Channels (Alexander et al., 2011).

Data Analysis

Data were expressed as log concentration-response plots. The contraction to all agonists was expressed in g, and measured from the stabilised U46619 response. Values for all figures refer to mean ± S.E.M with 95% confidence. Results were compared by two-way ANOVA or
Student’s unpaired *t*-test (Prism, GraphPad, San Diego, CA, USA). Differences were considered to be significant when the *P* value was < 0.05. *N* expresses the number of animals.

**Results**

**Effect of UDP-glucose, UDP and MRS2690 in porcine isolated pancreatic arteries**

To investigate the possible functional expression of P2Y\textsubscript{14} receptors and their role in porcine pancreatic arteries, agonists for this receptor were applied as cumulative concentrations. MRS2690, a selective P2Y\textsubscript{14} receptor agonist (0.1 µM to 30 µM), UDP-glucose (1 µM to 1 mM) and UDP (1 µM to 1 mM) were added after preconstriction with U46619. All of the agonists induced a concentration-dependent contraction with a rank order of potency of MRS2690 > UDP-glucose ≥ UDP. MRS2690 was significantly more potent, by approximately 10-fold, than UDP-glucose (*P* < 0.01, two-way ANOVA, Figure 1A), while UDP-glucose and UDP responses were equipotent (Figure 1A). Both UDP-glucose and UDP (P2Y\textsubscript{14} receptor agonists) separately induced significant attenuation of the contraction to UDP-glucose; for instance, the response to 100 µM UDP-glucose was decreased by 55 ± 7% in the presence of 100 µM UDP-glucose, and by 53 ± 7% in the presence of 100 µM UDP (*P* < 0.001, *n*=10-13, Figure 1B).

**Effect of PPADS and suramin on responses to UDP-glucose, UDP and MRS2690 in porcine isolated pancreatic arteries**

Responses to UDP-glucose, UDP and MRS2690 were characterised using the non-selective P2 receptor antagonists PPADS (10 µM) and suramin (100 µM) (Rayment *et al.*, 2007b). Both PPADS and suramin significantly enhanced the contractions evoked by UDP-glucose and UDP (Figure 2A, 2B). The contraction to 100 µM UDP-glucose was enhanced by 121 ± 38% (P <
0.001, n=7) and by 100 ± 23% (P < 0.001, n=8) in the presence of PPADS and suramin respectively (Figure 2A). The contraction to 1 mM UDP was enhanced by 180 ± 46% (P < 0.001, n=8), and by 154 ± 30% (P < 0.001, n=8) in the presence of PPADS and suramin respectively (Figure 2B). Suramin and PPADS failed to alter the contraction to MRS2690 (Figure 2C). In contrast, suramin and PPADS blocked the contraction to UTP, a P2Y₂ and P2Y₄ receptors agonist (von Kügelgen, 2006) (unpublished observations). UDP is a ligand at P2Y₆ receptors as well as P2Y₁₄ receptors. Therefore, the effect of UDP was examined in the presence of MRS2578 (10 µM), a P2Y₆ receptor selective antagonist (Mamedova et al., 2004).

The contraction evoked by UDP was unaffected at lower concentrations but was augmented at higher concentrations of UDP (supplementary information), while MRS2578 did not alter the responses to UDP-glucose or MRS2690 (supplementary information).

**Effect of PPTN, a selective high affinity antagonist of P2Y₁₄ receptor, on responses to UDP-glucose and MRS2690 in porcine isolated pancreatic arteries**

The responses to UDP-glucose and MRS2690 were examined in the presence of PPTN (1 µM), a selective high affinity antagonist of P2Y₁₄ receptor (Robichaud et al., 2011; Barrett et al., 2013). This compound significantly reduced the contraction evoked by UDP-glucose at basal tone (Supplementary information) and that by UDP-glucose and MRS2690 at raised tone (Figure 3A, 3B). PPTN inhibited the contraction to 100 µM UDP-glucose and to 10 µM MRS2690 by 55 ± 10% (P < 0.05, n=7) and by 46 ± 9% (P < 0.01, n=9) respectively (Figure 3A, 3B). The contraction to UTP was not altered in the presence of PPTN (Figure 3C). Typical traces, showing the effect of MRS2690 in the absence and in the presence of PPTN, are shown in Figure 3D.
Effect of endothelium removal on responses to UDP-glucose, UDP and MRS2690 in porcine isolated pancreatic arteries

The responses of UDP-glucose, UDP and MRS2690 were studied after the endothelium had been removed. The contractions induced by UDP-glucose, UDP and MRS2690 were significantly attenuated in the endothelium-denuded arteries (Figure 4). Removal of endothelium reduced the contractions to 1 mM UDP-glucose by 50 ± 7% (P < 0.001, n=12), that to 1 mM UDP by 61±11% (P < 0.001, n=15) and that to 30 µM MRS2690 by 41 ± 5% (P < 0.01, n=5) (Figure 4).

Effect of DUP 697 on responses to UDP-glucose, UDP and MRS2690 in porcine isolated pancreatic arteries

Because the contractions to P2Y14 receptor agonists were mainly endothelium-dependent, these were studied in the presence of DUP 697, a cyclooxygenase-2 (COX-2) inhibitor, since COX-2 facilitates the release of agents which are responsible for endothelium-dependent contraction. DUP 697 (3 µM) diminished the responses to UDP-glucose, UDP and MRS2690 to a similar extent as removal of the endothelium (Figure 5), while DUP 697 did not alter the contraction to U46619 (the preconstriction agent) or the contraction to ATP (data not shown). DUP 697 reduced the contraction to 1 mM UDP-glucose by 34 ± 10% (P < 0.001, n=11), that to 1 mM UDP by 38 ± 7.5% (P < 0.001, n=15) and that to 30 µM MRS2690 by 22.5 ± 13% (P < 0.01, n=4), (Figure 5).
The role of endothelium-derived contracting factors in the response to UDP-glucose in porcine isolated pancreatic arteries

The following experiments were carried out using mainly UDP-glucose or UDP due to the cost considerations involved with use of MRS2690. The possible involvement of thromboxane A₂, leukotrienes, endothelin-1 and PGF₂α, which can be released from endothelial cells (Mombouli & Vanhoutte, 1993; Kurahashi et al., 2003; Wong et al., 2009), in endothelially-mediated contraction to UDP-glucose was investigated. The contraction to UDP-glucose was not altered in the presence of nordihydroguaiaretic acid (NDGA) (10 µM), a lipoxygenase inhibitor (Figure 6A) or zafirlukast (10 µM), a leukotriene receptor inhibitor (Figure 6B). The contraction to UDP-glucose was reduced in the presence of BQ123 (1 µM), a selective ETₐ receptor antagonist; the response to 100 µM UDP-glucose was attenuated by 10 ± 3% (P < 0.05, n=14) in the presence of BQ123 (Figure 6C), which was only effective with intact endothelium (Supplementary information). The contraction to UDP-glucose was unaltered in the presence of BQ788 (1 µM), a selective ETₐ receptor antagonist (Supplementary information). In addition, UDP-glucose induced-contraction was reduced in the presence of L-655,240 (1 µM), a selective thromboxane A₂/prostaglandin endoperoxide receptor antagonist. The response to 100 µM UDP-glucose was inhibited by 38 ± 5% (P < 0.001, n=9) in the presence of L-655,240 (Figure 6D). These data indicate that UDP-glucose mediated-contraction occurs mainly via thromboxane and prostaglandins, with a lesser involvement of endothelin-1.

Effect of inhibition of calcium release and calcium entry on the response to UDP-glucose and UDP in porcine isolated pancreatic arteries

Binding of agonist to the recombinant P2Y₁₄ receptor leads to increase Ca²⁺ flux in some cells (Skelton et al., 2003; Gao et al., 2010). To test this in porcine pancreatic arteries, responses to
UDP-glucose and UDP were examined in the presence and absence of nifedipine (1 µM), an L-type voltage-gated calcium channel blocker, and thapsigargin (100 nM), a potent inhibitor of sarco-endoplasmic reticulum Ca\textsuperscript{2+}-ATPases which leads to depletion of intracellular calcium. Both of these inhibitors reduced the contraction evoked by 100 µM UDP-glucose, by 39 ± 5% (P < 0.001, n=15) in the presence of nifedipine, and by 25 ± 8% (P < 0.05, n=12-15) in the presence of thapsigargin (Figure 7A, 7B). Responses to 100 µM UDP were inhibited by 53 ± 2% (P < 0.001, n=9) in the presence of nifedipine, and by 36 ± 6% (P < 0.001, n=9) in the presence of thapsigargin (data not shown). Typical traces showing the effect of UDP-glucose in the absence and in the presence of nifedipine are shown in Figure 7C.

Effect of inhibition of the Rho-kinase pathway on the responses to UDP-glucose, UDP and MRS2690 in porcine isolated pancreatic arteries

Following the activation of P2Y\textsubscript{14} receptors, MLC may be phosphorylated because of upstream stimulatory RhoA/ROCK signalling (Amano et al., 1996; Hartshorne & Gorecka, 2011). To test the possible involvement of this pathway, experiments were conducted to study the contractions to UDP-glucose, UDP and MRS2690 in the presence of Y-27632 (5 µM), a selective inhibitor of the Rho-associated protein kinase p160ROCK. Y-27632 significantly inhibited the contraction evoked by UDP (Figure 8A), MRS2690 (Figure 8B) and UDP-glucose (data not shown). For instance, the response to 300 µM UDP was reduced by 50± 4% (P < 0.001, n=15, Figure 8A), that to 30 µM MRS2690 by 50 ± 15% (P < 0.001, n=9, Figure 8B) and that to 1 mM UDP-glucose by 52 ± 8% (P < 0.001, n=9, data not shown). The response to UDP-glucose was associated with an increase in the level of MLC\textsubscript{2} phosphorylation, after 30–60 s of treatment with 100 µM UDP-glucose, and returned to the basal level of phosphorylated MLC\textsubscript{2} from 120-300s (Figure 8C), which suggested an involvement of MLC\textsubscript{2} activation in the response to UDP-glucose P2Y\textsubscript{14} receptor signalling pathway. The ability of UDP-glucose (100
µM) or MRS2690 (10 µM) to elevate the MLC2 phosphorylation (after 30 s of treatment) was abolished in the presence of PPTN (1 µM), which shows that the ability of UDP-glucose or MRS2690 to elevate MLC2 phosphorylation in porcine pancreatic arteries is mediated by P2Y_{14} receptors (Figure 9).

**Effect of pre-constriction with U46619, and relaxation with forskolin, on the response to UDP-glucose in porcine isolated pancreatic arteries**

Agonist-promoted activation of G\_i and subsequent inhibition of adenylyl cyclase is one of the signalling responses of P2Y_{14} receptors. Therefore, the response to UDP-glucose was tested after exposure to U46619 and subsequent relaxation by forskolin (back to the baseline), involving elevation of intracellular cyclic AMP. UDP-glucose induced a greater contraction compared with the control, in which UDP-glucose was applied at basal tone without the tissues being exposed to U46619 or forskolin (Figure 10). The contraction to 100 µM UDP-glucose was enhanced by 930 ± 108% (P < 0.001, n=11) after the exposure to U46619 and forskolin (Figure 10A). In contrast, when responses to UTP, an agonist at P2Y\_2 and P2Y\_4 receptors (G\_q protein coupled receptors) were investigated in vessels exposed to U46619 and forskolin, there was no change in the contractions (Figure 10B). In addition, the response to UDP-glucose was not altered after contraction with U46619 and relaxation with SNP (100 µM), which elevates intracellular cyclic GMP (Roberts *et al.*, 1999). Typical traces showing the effect of UDP-glucose on basal tone and after the tissues had been contracted by U46619 and then relaxed with forskolin are shown in Figure 10C.

**Effect of UDP-glucose and MRS2690 on the cAMP level in porcine isolated pancreatic arteries**
On the basis that cAMP is involved in the contraction to P2Y\textsubscript{14} receptor agonists, we measured the cellular levels of this second messenger in pancreatic artery rings. We investigated the effects of UDP-glucose, MRS2690 and UTP (as a control, since it is coupled to G\textsubscript{q} protein) on cAMP level in the presence of U46619 + forskolin (to mimic the raised tone condition of the pharmacology experiments). UDP-glucose (1 mM) and MRS2690 (10 µM) induced a significant decrease in cAMP level in relative to the control (*P < 0.05, n=4), while UTP had no significant effect on cAMP levels (Figure 1).

**Discussion**

The current study presents evidence for the functional expression of contractile P2Y\textsubscript{14} receptors, sensitive to the endogenous nucleotides UDP-glucose and UDP in arteries of pig pancreas. Evidence from the contractile studies and the cAMP immunoassay is consistent with the ability of this receptor to inhibit adenylyl cyclase, while immunoblotting indicates the downstream involvement of MLC2. The contractile response was mediated largely by the endothelium with an involvement of endothelin, thromboxane A\textsubscript{2} and PGF\textsubscript{2α}.

Contractile studies showed that contractions to UDP-glucose and UDP were almost equipotent, whereas the contraction to MRS2690, a selective P2Y\textsubscript{14} receptor agonist, was approximately 10-fold more potent than that of UDP-glucose at the P2Y\textsubscript{14} receptor (Figure 1A). This is consistent with previous reports which suggest a 7-10 fold greater potency of MRS2690 over UDP-glucose (Jacobson \textit{et al.}, 2009; Gao \textit{et al.}, 2010). MRS2690 activity was observed at ≤ 10 µM; at 10 µM MRS2690 has been reported to be inactive at P2Y\textsubscript{2} receptors (Ko \textit{et al.}, 2009).
PPTN is a non-nucleotide, high affinity competitive antagonist at P2Y\textsubscript{14} receptors. It was assessed in HEK cells using a calcium mobilization assay and it inhibited UDP-glucose mediated signalling, and showed no effect on other P2Y receptors at concentrations up to 10 \( \mu \text{M} \) (Robichaud et al., 2011; Barrett et al., 2013). The responses to the P2Y\textsubscript{14} receptor agonists were examined in the presence of this antagonist. PPTN blocked the contractions induced by UDP-glucose and MRS2690 which confirms the involvement of P2Y\textsubscript{14} receptors in our arteries (Figure 3A, 3B).

The responses to the P2Y\textsubscript{14} receptor agonists were examined in the presence of the non-selective P2 receptor antagonists, suramin and PPADS. The non-selective antagonists induced a small increase in the contractions to UDP and UDP-glucose (Figure 2A, 2B). However, they failed to change the response to MRS2690 (Figure 2C). The lack of effect of suramin and PPADS appears to rule out an involvement of P2Y\textsubscript{2} and/or P2Y\textsubscript{4} receptors, since we have shown that they blocked the responses to UTP in porcine pancreatic arteries (unpublished observations) and other tissues (Rayment et al., 2007b). It is unclear why these antagonists enhanced the effects of P2Y\textsubscript{14} receptor agonists. However, it is clear that suramin and PPADS had different effect on UTP responses versus responses of MRS2690 and UDP-glucose indicating actions at different receptors.

Contractile responses to UDP-glucose, UDP and MRS2690 were significantly inhibited after the endothelium was removed (Figure 4), which indicated that the main expression of P2Y\textsubscript{14} receptor may be on the endothelial layer of porcine pancreatic arteries. Similarly, the P2Y\textsubscript{14} receptor has been reported to be expressed in endothelial cells of porcine coronary artery, human lung microvascular endothelial cells, and pulmonary artery vasa vasorum endothelial cells (Umapathy et al., 2010; Abbas et al., 2011; Lyubchenko et al., 2011). P2Y\textsubscript{14} receptor expression was barely detectable in mouse thoracic aorta (Kauffenstein et al., 2010); in
contrast, rat aortic smooth muscle cells show robust expression of the receptor, as observed in freshly isolated and cultured cells (Govindan et al., 2010).

To investigate the mechanism underlying the contraction mediated by P2Y14 receptors in pancreatic arteries, responses to UDP-glucose, UDP and MRS2690 were examined in the presence of DUP 697. As seen in Figure 5, the endothelium-dependent contractions were attenuated in the presence of the selective COX-2 inhibitor. Endothelial cells can release contractile factors (EDCFs), which may include thromboxane A2, PGF2α, leukotrienes and endothelin-1. Thromboxane A2 and PGF2α are released from the endothelium due to the activity of cyclooxygenase-2 (Mombouli & Vanhoutte, 1993; Wong et al., 2009). To characterise EDCFs involved in the contraction to UDP-glucose, experiments were conducted to study the responses to UDP-glucose in the presence of zafirlukast, BQ123, BQ788 and L-655,240. Only BQ123 and L-655,240 were able to inhibit the contraction evoked by UDP-glucose which indicated an involvement of thromboxane A2, prostaglandins and endothelin-1 (Figure 6). These agents, after being released from the endothelium, may act on their receptors on vascular smooth muscle cells (Wong et al., 2009).

The involvement of extracellular calcium influx and calcium released from sarcoplasmic reticulum (SR) as a part of the response to P2Y14 receptors activation has been reported (Verin et al., 2011). In addition, calcium-induced release of calcium from SR and influx of external Ca2+ in excitation-contraction in response to some activated receptors have been also reported (Fabiato, 1983; Li et al., 2003). In porcine pancreatic arteries, contractions to UDP-glucose (Figure 7A, B) and UDP (data not shown) were significantly decreased in the presence of nifedipine or thapsigargin, which identified an involvement of elevated intracellular calcium level. Collectively, our results suggest that when UDP-glucose, UDP and MRS2690 act at the P2Y14 receptors, which are expressed mainly on the endothelium, the intracellular Ca2+ levels may be elevated; this may then activate endothelin-1 and phospholipase A2 which liberates
arachidonic acid, which is then converted by the activity of COX-2 to produce the contractile agents, thromboxane A₂ and prostaglandin, which bind to receptors on vascular smooth muscle cells to induce contraction.

A number of studies have considered the signalling mechanism underlying the functional response of P₂Y₁₄ receptors (Harden et al., 2010; Sesma et al., 2012). Recent reports claimed that UDP-glucose promotes concentration-dependent activation of RhoA in isolated human neutrophils (Sesma et al., 2012). This was tested in porcine pancreatic arteries when responses were investigated in the presence of Y-27632; this compound inhibited the contraction evoked by UDP-glucose, UDP and MRS2690 (Figure 8A, 8B), which showed an involvement of RhoA in the response to P₂Y₁₄ receptor agonists. Activation of RhoA leads to phosphorylation of MLC and subsequently contraction of arteries in a calcium-independent manner (Amano et al., 1996; Hartshorne & Gorecka, 2011). Accordingly, when UDP-glucose or MRS2690 were incubated with the tissues, the level of phosphorylated MLC2 was elevated, but this elevation was abolished in the presence of PPTN, confirming that it is happening through the activation of P₂Y₁₄ receptors (Figure 8C, 9).

It is well established that the P₂Y₁₄ receptor is coupled to Gᵢ protein, leading to the inhibition of forskolin-stimulated adenylyl cyclase activity, and hence inhibition of the cyclic AMP level. Accordingly, the P₂Y₁₄ receptor is pertussis toxin-sensitive (PTX) (Jacobson et al., 2009). It is notoriously difficult to successfully block Gᵢ coupled receptors with PTX in isolated blood vessels, as we have also found. However, in tissues which had been preconstricted with U46619 and relaxed with forskolin (to elevate the cAMP levels), subsequent addition of UDP-glucose produced a significantly greater contraction compared with the controls (UDP-glucose added at basal tone, or UTP applied after preconstriction with U46619 and relaxation with forskolin) (Figure 10), consistent with an involvement of Gᵢ coupled receptors. Other purine receptors,
namely P2Y\textsubscript{1}, P2Y\textsubscript{2}, P2Y\textsubscript{4}, P2Y\textsubscript{6} receptors, are generally G\textsubscript{q} protein-coupled. Furthermore, relaxation with SNP (to elevate cGMP levels) after preconstriction with U46619 had no effect on the contractile response to UDP-glucose (data not shown). These findings together with the data obtained from cAMP assay (Figure 11) indicate that the enhanced contraction to UDP-glucose is mainly dependent on the agonist's ability to lower cyclic AMP levels.

Reduction in pancreatic blood flow has been observed in acute and chronic pancreatitis and some other pancreatic diseases (Satoh et al., 2000; Nguyen et al., 2010), implicating pancreatic tissue perfusion as an important factor in pathogenesis of pancreatic diseases and symptoms. There is increasing evidence for the role of purinergic signalling in the pathophysiology of the pancreas (Burnstock & Novak, 2012). Drugs designed to target specific component of purinergic system may be of relevance to the management of pancreatitis, cystic fibrosis, pancreatic cancer and diabetes.

In conclusion, this study has shown a novel vasocontractile action of UDP-glucose which appears to be mediated by the P2Y\textsubscript{14} receptor in porcine isolated pancreatic arteries. P2Y\textsubscript{14} receptors induce contraction via an involvement of endothelin-1, thromboxane A\textsubscript{2} and prostaglandins released from the endothelium. In addition, P2Y\textsubscript{14}-mediated contraction involves the activation of Rho kinase, and the subsequent phosphorylation of MLC2. The ability of P2Y\textsubscript{14}-receptor agonist to inhibit cAMP level indicates P2Y\textsubscript{14} receptor coupling to G\textsubscript{i} proteins. This study identifies a novel role for the P2Y\textsubscript{14} receptor as a vasocontractile P2 receptor.
