Non-conventional *trans*-Platinum Complexes Functionalized with RGD

Peptides: Chemical and Cytotoxicity Studies

Maria Angeles Medrano^a, Maurício Morais^{b,c}, Vera F. Ferreira^b, João D. G. Correia^b, António Paulo^b, Isabel Santos^b, Carmen Navarro-Ranninger^a, Amparo Alvarez Valdes^a, Angela Casini^d, Filipa Mendes^{b*}, Adoración G. Quiroga^{a*}

Abstract: In order to target platinum complexes to cancer cells, **trans-Pt(II)** or **trans-Pt(IV)** complexes were bioconjugated to the cyclic peptide cRGDfK (cRGD), with affinity for $\alpha_v\beta_3$ integrin receptors, through their 4-picolinic acid spectator ligands. To tackle this goal, the Pt(II) and Pt(IV) precursors were activated at their carboxylic acid function and further reacted with the cRGDfK peptide, to afford the bioconjugates **Pt(II)-cRGD** and **Pt(IV)-cRGD**, respectively. **Pt(II)-cRGD** was studied by ¹⁹⁵Pt-NMR that confirmed the presence of the Pt(II) center. In contrast, the characterization of **Pt(IV)-cRGD** was not possible due to the tendency of this complex to undergo reduction to Pt(II) in solution. Thus, only the **Pt(II)-cRGD** complex was used for further biological studies, and it exhibited some cytotoxic activity against the HUVEC cell line, with the highest levels of $\alpha_v\beta_3$ expression. However, no improved effects were observed with respect to the **Pt(II)-pic** precursor. Studies by ICP-MS showed enhanced intracellular accumulation for **Pt(II)-cRGD** with respect to **Pt(II)-pic** in cancer cells. Overall, these results show that while Pt(II) bioconjugation enhances compound's uptake, it did not translate into an increase in cytotoxicity.

Introduction

Metal-based anticancer agents are major components in the chemotherapeutic regime of many tumoral diseases. Platinum complexes are among the most used metalodrugs due to the widespread usage of cisplatin in the clinical setting. However, the clinical efficiency of cisplatin is hampered due to its low solubility, side effects, and poor activity versus certain tumors (tumor resistance).^[1] In view of these limitations, research has been extended to new platinum analogues with the aim of overcoming these unwanted effects.^[2] Most of this research has been performed with *cis* configuration because initial research reported a lack of activity of transplatin. However, several exceptions for non-conventional *trans*-[PtCl₂(L)(L')] complexes were reported, indicating that synthetic variations in the coordinating ligands could lead to new active species.^[3] Based on aliphatic amines as spectator ligands, our research was also

able to demonstrate that active *trans* Pt(II) complexes were achievable.^[4, 5]

Both for cisplatin and trans-platinum like complexes, drug targeting strategies are considered important tools to enhance their selectivity and efficacy as antitumoral agents. Receptors associated with cell growth and division are often overexpressed in tumors, being therefore relevant for drug targeting. In particular, peptide receptors are overexpressed in certain tumors, as compared to endogenous expression levels, being such receptors relevant targets to achieve a specific accumulation of metalodrugs in tumor cells.^[6] The examples of Pt compounds carrying bioactive peptides for specific delivery of Pt remain scarce. Reedijk et al have proved how platinum complexes with a broad library of dipeptides and tripeptides showed cytotoxic activity against cancer cell lines. Although such activity was not higher than cisplatin, structural variations on this tested series demonstrated a clear influence in the activity of the series.^[7-9] With the same aims, Metzler-Nolte and coworkers achieved different series of metal compounds' bioconjugates using cell penetrating peptides and other examples in a drug targeting and delivery strategy.^[10, 11]

Other examples found in the literature have explored a different series of receptors: the integrin family. Integrins are heterodimeric receptors that play a pivotal role in many cell-cell and cell-extracellular matrix interactions.^[12, 13] They consist on transmembrane glycoproteins that contain two non-covalently bound α and β subunits. The integrin receptor $\alpha_v\beta_3$, also known as the vitronectin receptor, is expressed in endothelial cells and modulates cell migration and survival during angiogenesis. Being overexpressed in a variety of tumor cell types, such as glioblastoma, melanoma, ovarian, breast and prostate cancer, it potentiates tumor invasion and metastasis.^[14] The $\alpha_v\beta_3$ -integrin recognizes selectively extracellular matrix proteins, such as vitronectin or fibronectin, which contain the exposed Arg-Gly-Asp (RGD) sequence.^[15] The discovery of the canonical RGD sequence motivated an intense research work on small peptide-based molecules aimed at targeted drugs for antiangiogenic therapy.

Lippard et al used an approach exploring the targeting ability of peptides such as linear and cyclic RGD and Asn-Gly-Asp (NGR), and synthesized a Pt(IV) series comprising mono and bifunctionalized complexes, which positively improved the cisplatin activity as a consequence of the peptide release once the Pt(IV) compound reduces to cisplatin (Pt(II)).^[16] More recently, other Pt(IV) complexes functionalized with cyclic and multimeric RGD containing-peptides have been described. Interestingly, conjugation of a photoactivatable Pt(IV) pro-drug to a cyclic RGD-containing peptide, led to increased phototoxicity in melanoma cancer cells overexpressing the $\alpha_v\beta_3$ -integrin receptor.^[17] Other approach explored the possibility of enhancing the selectivity and potency of a Pt(IV) derivative of

picoplatin by the conjugation with monomeric and multimeric cRGD peptides.^[18]

Previously, we have shown that some non-classical *trans*-Pt(II) complexes with isopropylamine (ipa) and pyridine derivatives are active in cisplatin-resistant cell lines,^[4, 5] as well as the corresponding Pt(IV) counterparts. Herein, we describe our attempts to functionalize these Pt(II)/Pt(IV) complexes with the cyclic RGD peptide cRGDfK, aiming to obtain compounds with enhanced selectivity towards their cytotoxic action (Figure 1).

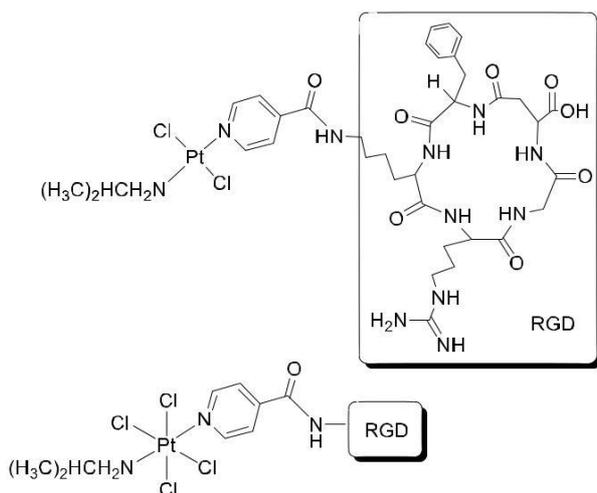

Figure 1. Pt(II)-cRGD and Pt(IV)-cRGD proposed complexes.

We have taken into consideration that cyclic RGD peptides are more efficient in targeting endothelial cells and have been extensively used for research, therapy, and diagnosis of neoangiogenesis.^[19] Additionally, cRGDfK in particular, can be easily attached to the metal moieties via the lysine side chain, while preserving its biological activity.^[19, 20]

To achieve our goal, we hypothesized that the conjugation of cRGDfK to the *trans*-Pt(II) or *trans*-Pt(IV) complexes, through a 4-picolinic acid spectator ligand, would lead to Pt bioconjugates with the ability of specifically recognizing cells overexpressing $\alpha_v\beta_3$ receptors, with a consequent enhancement of the cytotoxic activity against the same cell lines.

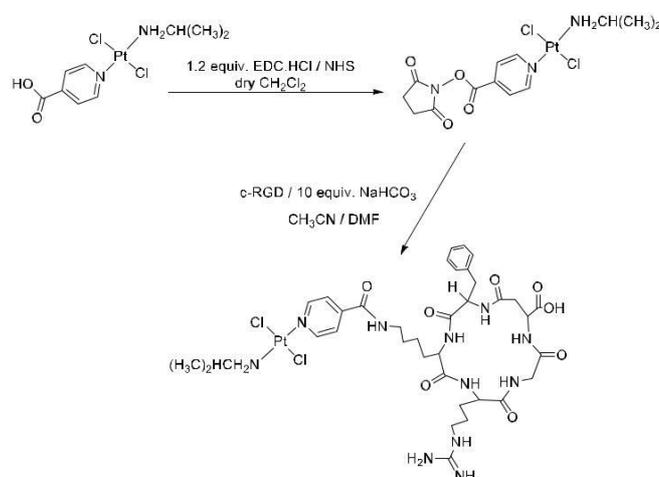

Results and Discussion

Synthesis and Characterization

By studying the functionalization of related Pt(II) and Pt(IV) complexes with the same cRGDfK derivative, we have considered that the intracellular reduction of the RGD-containing Pt(IV) pro-drug could contribute to further improve the selectivity of the cytotoxic action of the Pt(II) unit carrying the bioactive peptide. To clarify this issue, the comparison of the biological behaviour of the resulting Pt(II) and Pt(IV) bioconjugates would be of the greatest importance.

The same strategy was used to functionalize the Pt(II) and Pt(IV) precursors with the RGD derivative, which comprised the prior activation of the carboxylic function of the 4-picolinic acid coordinated to Pt(II) or Pt(IV), followed by the subsequent coupling of the peptide. Hence, the synthesis of the metallated bioconjugates started with the peptide synthesis by a two-step method. First, the automated synthesis of the linear RGD peptide was achieved in solid-phase, followed by the cyclization in solution using strategies reported before.^[21] The final cyclic peptide was characterized by mass spectrometry.

The coupling of the Pt(II) and Pt(IV) precursors, herein designated as **Pt(II)-pic** and **Pt(IV)-pic**, respectively, to the cRGD peptide comprised the formation *in situ* of an NHS-activated ester of the coordinated 4-picolinic acid, as depicted in Scheme 1.

Scheme 1. Synthesis pathway of the **Pt(II)-cRGD** complex (EDC = N-(3-Dimethylaminopropyl)-N'-ethylcarbodiimide; NHS = N-hydroxysuccinimide)

Thereafter, the resulting Pt(II) and Pt(IV) activated esters were reacted with the cRGD derivative to afford the final Pt(II) and Pt(IV) bioconjugates. In the case of the Pt(II) bioconjugate, further purification (including HPLC) yielded the desired complex, **Pt(II)-cRGD** (Scheme 1), as detailed in the experimental section. The chemical identity of **Pt(II)-cRGD** was confirmed by ¹⁹⁵Pt-NMR and mass spectrometry (see Figure 2 and Figure S1).

According to ESI-MS analysis of an aliquot of the reaction mixture, the anchoring of the cRGD peptide to the Pt(IV) complex resulted in the formation of a Pt(IV) bioconjugate, **Pt(IV)-cRGD**, with the expected molecular ion peak (ESI-MS (+) (m/z): 1144,28 [M+CH₃CN+H]⁺, calc. for C₃₆H₅₃Cl₄N₁₁O₈Pt 1102.25 [M]⁺; see experimental peaks in Figure S2)

Moreover, the HPLC analysis of the crude reaction mixture showed the presence of a major peak at $t_R = 25.0$ min, which is clearly different from the retention time exhibited by **Pt(II)-cRGD** ($t_R = 19.8$ min) under the same analytical conditions.

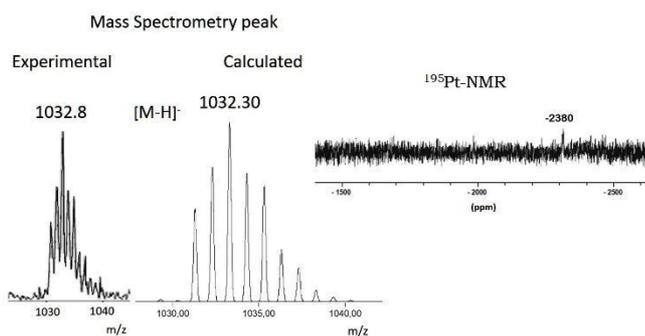

Figure 2. Characterization of the **Pt(II)-cRGD** complex: left: experimental and calculated molecular $[M-H]^{-}$ peaks; right: ^{195}Pt -NMR spectra in MeOD.

Unfortunately, all the attempts to record the ^{195}Pt -NMR of Pt(IV)-cRGD were not successful (see Figure S3). Nuclear Magnetic Resonance (NMR) long accumulation experiments (overnight) finally afforded a small signal (that became stronger along time) in the Pt(II) area corresponding to the **Pt(II)-cRGD** complex (see Figures S4 and S5). These findings indicated that **Pt(IV)-cRGD** is not stable in solution being reduced to its **Pt(II)-pic** counterpart. For this reason, no further studies were performed with this **Pt(IV)-cRGD** complex.

Antitumoral activity in human cancer cell lines

The antiproliferative properties of **Pt(II)-cRGD** and **Pt(II)-pic** were assayed by monitoring their ability to inhibit cell growth. Cytotoxic activity was determined on different human cancer cell lines: breast carcinoma cells (MDAMB231 and MCF7), ovarian carcinoma cells (A2780 and SKOV3) and human adenocarcinoma (A549). This diverse panel was chosen in order to perform the cytotoxicity evaluation in cell lines of different tumoral origins and with different levels of $\alpha\text{v}\beta_3$ -integrin expression.^[22] Additionally, the non-tumoral HUVEC human endothelial primary cell line overexpressing the $\alpha\text{v}\beta_3$ -integrin receptor was also tested in the same assay. A comparison between the activity of reference drug cisplatin (CDDP) and the activity of these metal compounds was performed. Using an appropriate range of concentrations, dose-response curves after long-term (72 h) exposure were obtained. From the experimental values, the IC_{50} values for the compounds were calculated (Table 1).

In the human cell lines with no detectable expression of $\alpha\text{v}\beta_3$ -integrin, the new platinum(II) complex coupled to the cRGD peptide, **Pt(II)-cRGD**, did not show any measurable cytotoxic activity, neither an increase of such activity compared with the parental complex. In fact, in almost all cell lines tested, the conjugation of the Pt(II) complex to the carrier peptide resulted in a marked reduction of the cytotoxic activity.

Worth of note is that in the HUVEC cell line, which has the highest levels of $\alpha\text{v}\beta_3$ expression, the **Pt(II)-cRGD** complex exhibited some cytotoxic activity. Nevertheless, **no marked increase in antiproliferative effects of Pt(II)-cRGD was detected in comparison with the respective parental complex in the HUVEC cells.** In fact, the IC_{50} measured for **Pt(II)-cRGD** is only

~1.4 times higher than the value obtained for Pt(II)-pic under the same conditions. We have reasoned that these overall results could possibly reflect the decreased uptake of Pt(II)-cRGD compared with the parental Pt(II) complex in the cell lines presenting a lower expression of $\alpha\text{v}\beta_3$ -integrin receptors, at variance with what has been observed in the case of HUVEC cells, where the compound could undergo an increased uptake due to the overexpression of the same receptors. To clarify this issue, we have performed cell uptake studies for the parental complex (Pt(II)-pic) and respective RGD derivative (Pt(II)-cRGD) in selected cell lines, as described below.

Table 1. IC_{50} values (expressed in μM) for Pt(II)-cRGD complex, its precursor and CDDP, as determined by the MTT assay after 72 h of incubation of the compounds at 37 °C with tumoral and non-tumoral cells

	Cell lines ($\alpha\text{v}\beta_3$ expression)					
	A2780 (-)	A549 (-)	MCF7 (-)	MDA MB231 (+)	SKOV3 (+)	HUVEC (+++)
Pt(II)-pic	87.67 ± 1.2	>100	60.3 ± 1.2	51.8 ± 1.3	>100	60 ± 11
Pt(II)-cRGD	>100	>100	>100	>100	>100	85 ± 15
cDDP	1.5 ± 0.2	10.8 ± 0.8	38.2 ± 1.3	8.5 ± 1.1	13.8 ± 1.6	-

Cellular uptake evaluation

An important parameter in the cytotoxic activity of metallo drugs is the uptake and accumulation of the metal in cells. In order to rationalize the results of the cytotoxicity studies, and taking into consideration that the new platinum complex is a targeted metal-peptide conjugate, cellular uptake experiments were performed in the MCF7 and HUVEC cells lines. These cells were chosen because they present very different levels of expression of $\alpha\text{v}\beta_3$ ^[22] and, importantly, the parental complex presents similar cytotoxicity values against both cell lines.

After incubation of the cell lines with the complexes for 24 h, cells extracts were collected and the intracellular accumulation of Pt was measured by inductively-coupled plasma mass spectrometry (ICP-MS). The normalized results out of a single experiment are presented in Figure 3. There is a higher accumulation of platinum in HUVEC cells after exposure to both **Pt(II)-pic** and **Pt(II)-cRGD** when compared with MCF7 cells. In the case of the parental complex there is 100x more uptake in primary HUVEC cells (0.17 nmol Pt per 10^6 cells) than in the breast cancer cells (0.0015 nmol Pt per 10^6 cells), albeit presenting similar IC_{50} values in the two cell lines. Platinum accumulation after exposure to the peptide-metal conjugate was more than 36x times higher in HUVEC cells than in MCF7 cells (1.08 versus 0.0299 nmol Pt per 10^6 cells). This result is in line with the cytotoxicity studies and with the lower level of expression of $\alpha\text{v}\beta_3$ integrin in MCF-7 cells compared with HUVEC cells.

It is important to notice that **Pt(II)-cRGD** showed the greatest increase of cell uptake relatively to the parental complex in the MCF7 cell line, having the lowest expression of the integrin receptor. However, the cell uptake values of both compounds are much higher in the integrin-positive HUVEC cell line, hampering a reliable comparison of the results obtained in the two different cell lines.

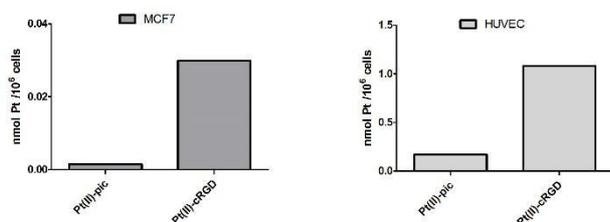

Figure 3. Cell accumulation of platinum in HUVEC and MCF7 cells after exposure to **Pt(II)-cRGD** and parental Pt(II) complex (50 μ M, 24 h). The platinum content is normalized to the cell number. The reported results are from one experiment.

In the case of the HUVEC cell line, we believe that the enhanced intracellular accumulation of **Pt(II)-cRGD** could be due to its interaction with the targeted receptor at the cell surface. To validate this hypothesis HUVEC cells were incubated with **Pt(II)-cRGD** in the presence of an excess of free cRGD to block the interaction with α ν β β integrin. We observed a decrease in platinum accumulation of ~40% (1.08 versus 0.61 nmol Pt per 10⁶ cells for **Pt(II)-cRGD** alone and with excess of free cRGD). This result points out for the possible contribution of specific mechanisms of uptake mediated by the α ν β β receptor.

Conclusions

The functionalization of a **Pt(II)-(ipa)** core complex with the cyclic peptide cRGDfK has been achieved and the characterization completed. The resulting bioconjugate, **Pt(II)-cRGD**, did not manifest a substantial increase in cytotoxic activity, as we originally expected, including towards the HUVEC cell line, overexpressing integrin receptors. However, **Pt(II)-cRGD**'s uptake was substantially increased in cancer cells, and in HUVEC was blocked by excess of cRGD. These results indicate a possible selective and specific tumor uptake for the bioconjugate **Pt(II)-cRGD**. Further studies will be required to elucidate the intracellular fate and stability of this new platinum complex.

Experimental Section

Reagents and Materials

The platinum complexes *trans*-[PtCl₂(4-picolinic acid)(isopropylamine)], **Pt(II)-(ipa)** and *trans*-[PtCl₄(4-picolinic acid)(isopropylamine)], **Pt(IV)-(ipa)**

were prepared as described elsewhere.^[4, 5] The linear peptide was synthesized using the Fmoc (9-fluorenylmethoxycarbonyl) strategy on a CEM 12-Channel Automated Peptide Synthesizer. Fmoc-amino acids were purchased from CEM. The acid labile 2-chlorotrityl chloride resin, benzotriazol-1-yl-oxytrityrrolidinophosphonium hexafluorophosphate (PyBop) and 1-hydroxy-1H-benzotriazole (HOBt) were purchased from Novabiochem (Merck), whereas N,N-diisopropylethylamine (DIPEA), N-(3-Dimethylaminopropyl)-N'-ethylcarbodiimide hydrochloride (EDC.HCl) and N-hydroxysuccinimide (NHS) were purchase from Sigma-Aldrich (Spain).

Chromatographic systems

HPLC analyses were performed on a Perkin Elmer LC pump 200 coupled to a Shimadzu SPD 10AV UV/Vis and to a Berthold-LB 509 radiometric detector. Analytical control and semi-preparative purifications of the linear and partially protected RGD and peptide conjugates was achieved on Supelco Discovery Bio Wide Pore C18 (250 x 4.6 mm, 5 μ m) and Supelco Discovery Bio Wide Pore C18 (250 x 10 mm, 10 μ m)) with a flow rate of 1.0 mL min⁻¹ or 2.0 mL min⁻¹ (gradient B), respectively.

Applied binary gradients

Gradient A (Mobile phase: A = aqueous 0.1% CF₃COOH and B = MeOH): 0-3 min, 0% mobile phase B; 3-3.1 min, 0 – 25 % mobile phase B; 3.1-9 min, 25 % mobile phase B; 9-9.1 min, 25 – 34 % mobile phase B; 9.1-20 min, 34 – 100 % mobile phase B; 20-25 min, 100 % mobile phase B; 25-25.1 min, 100 – 0 % mobile phase B; 25.1-30 min, 0 % mobile phase B.

Gradient B (Mobile Phase A = H₂O and B= ACN): 0-35 min, 55-100 % B; 35-37 min, 100 % B; 37-38 min, 100-55% B; 38-40 min, 55 % B.

Gradient C (Mobile Phase A = H₂O and B= ACN): 0–3 min, 0 % B; 3 – 30 min, 0-50 % B; 30 –33 min, 50 % B; 33–33.1 min, 100 % B; 33.1–37 min, 100% B, 37-38 min, 100-0 % B, 38-40 min, 0% B.

Peptide Synthesis

The linear sequence was assembled by solid-phase peptide synthesis (SPPS) on 2-chlorotrityl chloride resin according to the Fmoc strategy. After peptide cleavage from the resin under mild acidic conditions (1% TFA/CH₂Cl₂), the solution was concentrated to 5% of the initial volume and a white solid was precipitated with cold water in an ice bath. The partially protected peptide was washed consecutively with water (three times), 5% aqueous NaHCO₃ (twice), water (three times), 0.05 M KHSO₄ (twice), and water (six times) and lyophilized. RP-HPLC (220 nm, *gradient B*): 95% (t_R = 10.4 min). ESI-MS (+) (m/z): 1031.1 [M+H]⁺, calc. for C₄₉H₇₅N₉O₁₃S, 1030.24.

Cyclization was performed via in situ activation with 2 equiv. of PyBop and with 10 equiv. of DIPEA as solid base under high-dilution conditions (5 mM) in CH₂Cl₂/DMF (11:1) for 16 h. The reaction mixture was purified by semipreparative RP-HPLC (220 nm, *gradient A*). After evaporation of the solvent, the compounds were deprotected with a standard cocktail mixture (95% TFA, 2.5% triisopropylsilane, 2.5% H₂O) and precipitated with ice-cold diethyl ether. The compound was purified by preparative RP-HPLC (method B). After evaporation of the organic solvent, the compound was lyophilized and characterized by ESI-MS.

RP-HPLC (220 nm, *gradient C*): 95% (t_R = 14.0 min). ESI-MS (+) (m/z): 604.6 [M+H]⁺, calc. for C₂₇H₄₁N₉O₇, 603.67.

General procedure to conjugate RGD to platinum Complexes

The carboxylic acid of *trans*-[PtCl₂(4-picolinic acid)(isopropylamine)] and *trans*-[PtCl₄(4-picolinic acid)(isopropylamine)] (0.01 mmol) was activated with 1.2 equiv. of EDC.HCl and N-hydroxysuccinimide (NHS) in dry CH₂Cl₂. After reacting at room temperature for 16 h under nitrogen, the solvent was evaporated and the yellow pail solid was washed with water to remove the urea by product. The solid was vacuum-dried. The activated ester were dissolved in CH₃CN and added dropwise to a DMF solution (500 µL) containing the *cyclo*-RGD (0.003 g, 0.005 mmol) and 10 equiv. of NaHCO₃. After stirring for ~3 h, the solvent was evaporated and the yellow solid was washed with CH₂Cl₂, dried, dissolved in water and purified by analytical RP-HPLC. After purification, RP-HPLC analysis (method B) was used to assess the purity (> 95%) of the recovered RGD-containing Pt complexes (see Figure S6).

Cyclo-RGD conjugate-Pt^{II}

RP-HPLC (220 nm, *gradient C*): t_R = 19.8 min. ESI-MS (-) (m/z): 1068.7 [M+Cl]⁻ and 1032.8 [M-H]⁻, calc. for C₃₆H₅₃Cl₂N₁₁O₈Pt 1033.86.

δ(¹⁹⁵Pt, 64.53 MHz, MeOD, Na₂PtCl₆): -2380 ppm.

Yield: 10 % (487 µg, 0.0005 mmol; εPhe (257 nm) = 200 L mol⁻¹ cm⁻¹)

Cyclo-RGD conjugate-Pt^{IV}

RP-HPLC (220 nm, *gradient C*): 95% (t_R = 25.0 min). ESI-MS (+) (m/z): 1146.8 [M+ACN+H]⁺, calc. for C₃₆H₅₃Cl₄N₁₁O₈Pt 1104.76.

Yield: 6 % (336 µg, 0.0003 mmol; εPhe (257 nm) = 200 L mol⁻¹ cm⁻¹)

Cell culture

Human Umbilical Vein Endothelial Cells (HUVEC) were cultured in supplemented EGM medium (Lonza). Human ovarian epithelial cancer cell lines (A2780 and SKOV3) were maintained in RPMI 1640 Medium. Human breast carcinoma cells (MCF-7 and MDA MB 231) and human adenocarcinoma (A549) were grown in DMEM. RPMI and DMEM culture mediums were supplemented with 10% heat-inactivated fetal bovine serum (FBS) and 1% penicillin/streptomycin antibiotic solution. All culture mediums and supplements, except when indicated, were from Gibco, Invitrogen, UK. Cells were cultured in a humidified atmosphere of 95% air and 5% CO₂ at 37 °C (Heraeus, Germany).

Cytotoxicity

The potential as antitumoral agents was explored by the evaluation of their effects on cellular proliferation using the [1-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium] (MTT) assay. Cells were seeded in 96-well culture plates at a density of 1.5 x 10⁴ to 2.5 x 10⁴ cells/well (depending of the cell line) and left to adhere overnight at 37 °C. Cells were then incubated with the Pt complexes at different concentrations (0-200 µM) during 72h at 37 °C and 5 % CO₂. All tested compounds were first solubilized in DMSO (20 mM stock solution) and then diluted in culture medium for the assay, with the percentage of solvent in the culture never exceeding 0.1 %. After incubation, the compounds were removed and cells washed with PBS (200µL). The cellular viability was assessed by incubating cells with MTT (200 µL of 0.5 mg/mL solution in Modified Eagle's Medium without phenol red) during 3h at 37 °C. The MTT solution was removed and the insoluble and blue formazan crystals formed were dissolved and homogenized with DMSO (200 µL/well). The absorbance

of this colored (purple) solution was quantified by measuring the absorbance at 570 nm, using a plate spectrophotometer (Power Wave Xs; Bio-Tek). A blank solution was prepared with DMSO alone (200 µL/well). Each test was performed with at least six replicates. These results were expressed as percentage of the surviving cells in relation with the control incubated without compound. The maximum concentration of DMSO used in compounds solutions (0.1 %) was not cytotoxic. IC₅₀ values were determined using the Graph Pad Prism software and expressed in micromolar concentrations.

ICP-MS

To explore the uptake of selected complexes and their intracellular distribution, cells were exposed to each complex (50 µM) for 24 h at 37 °C, and then washed with cold PBS, collected by scrapping and centrifuged to obtain a cellular pellet. For the blocking experiments, an excess of cRGD (1mM) was used. The Pt content in the cell pellet was measured, after digestion, by ICP-MS on a ICP-MS NexION 300xx Perkin-Elmer instrument, with ¹⁸⁷Rhenium used as internal standard. Briefly, samples were digested with ultrapure HNO₃ (65 %), H₂O₂ and HCl, then evaporated and resuspended in ultrapure water to obtain a 2.0% (v/v) nitric acid solution. The relative standard deviation of the measurements (different aliquots from the same mother solution) was between 0.5 and 2.1%.
